EnsMOD: A Software Program for Omics Sample Outlier Detection

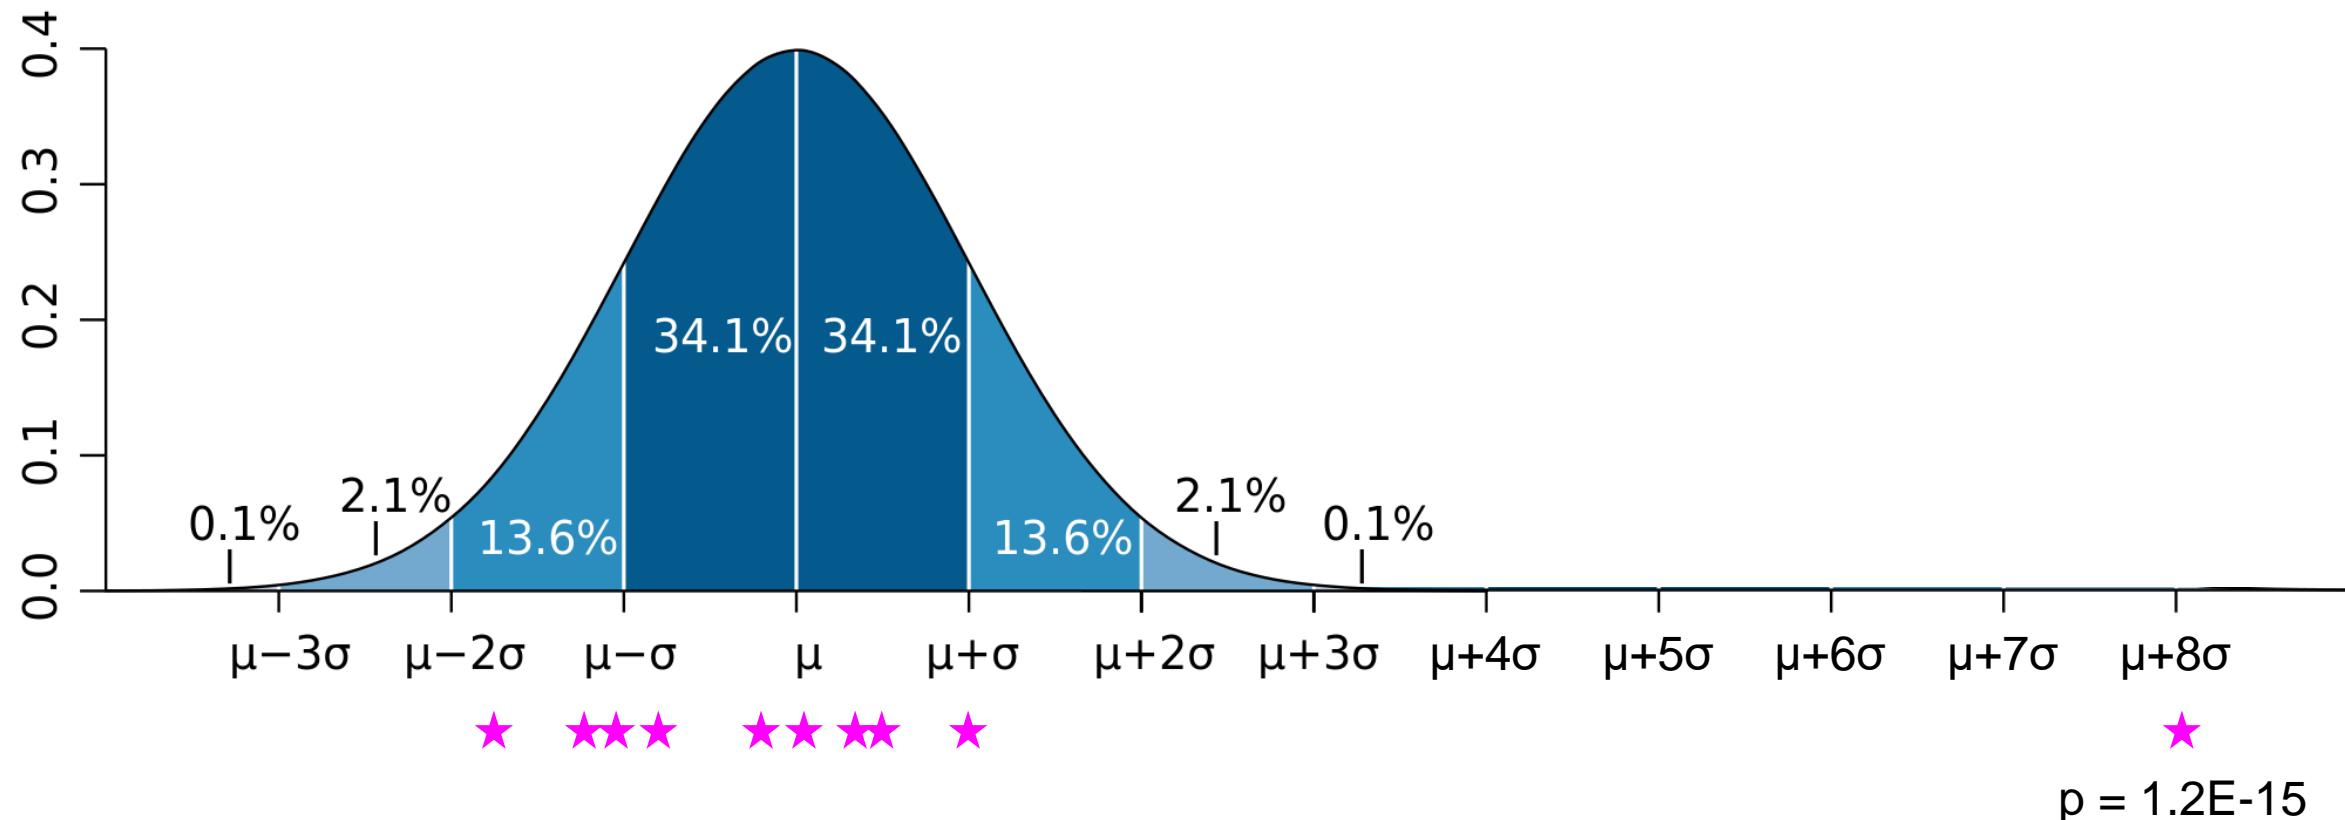

NATHAN P. MANES,* JIAN SONG,* and ALEKSANDRA NITA-LAZAR

ABSTRACT

Detection of omics sample outliers is important for preventing erroneous biological conclusions, developing robust experimental protocols, and discovering rare biological states. Two recent publications describe robust algorithms for detecting transcriptomic sample outliers, but neither algorithm had been incorporated into a software tool for scientists. Here we describe Ensemble Methods for Outlier Detection (EnsMOD) which incorporates both algorithms. EnsMOD calculates how closely the quantitation variation follows a normal distribution, plots the density curves of each sample to visualize anomalies, performs hierarchical cluster analyses to calculate how closely the samples cluster with each other, and performs robust principal component analyses to statistically test if any sample is an outlier. The probabilistic threshold parameters can be easily adjusted to tighten or loosen the outlier detection stringency. EnsMOD can be used to analyze any omics dataset with normally distributed variance. Here it was used to analyze a simulated proteomics dataset, a multiomic (proteome and transcriptome) dataset, a single-cell proteomics dataset, and a phosphoproteomics dataset. EnsMOD successfully identified all of the simulated outliers, and subsequent removal of a detected outlier improved data quality for downstream statistical analyses.

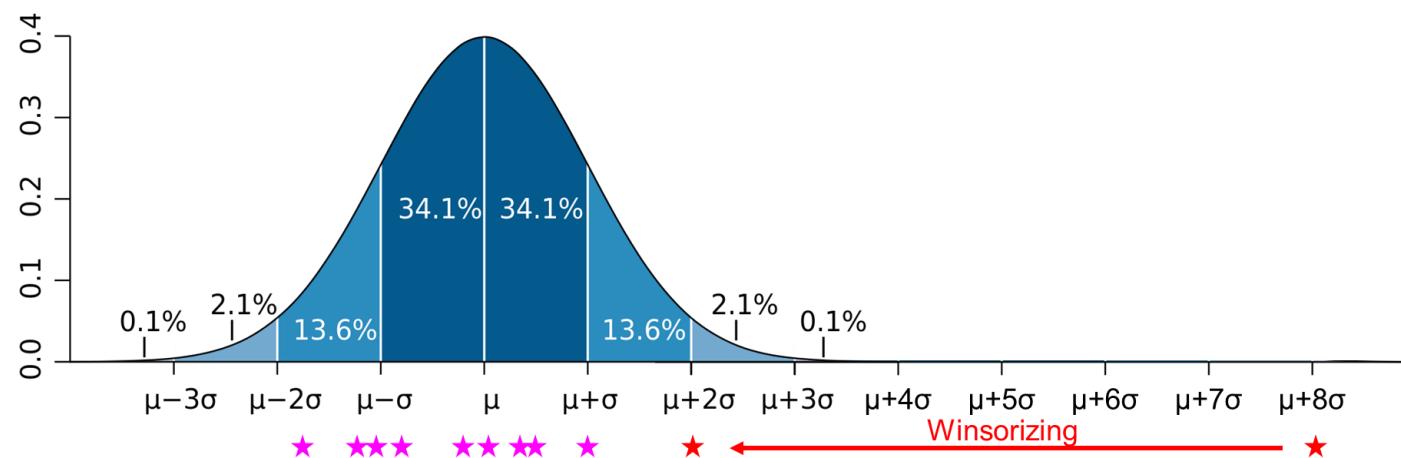

An Outlier is a Statistical Anomaly

“An outlier is an observation that deviates so much from other observations as to arouse suspicion that it was generated by a different mechanism.”

Outlier Mitigation Strategies

- Do nothing (might skew downstream statistics)
- Increase the number of samples (wash out the effect of the outliers)
- Redo the entire experiment from scratch
- Identify the outlier mechanism (if it is reproducible)
 - Biological outlier: Identify a novel biological mechanism
 - Technical outlier: Improve protocol to prevent future outliers
- Outlier winsorizing
- Outlier removal (statistical “truncation”)

Examples of Proteomics Sample Outliers

- LC-MS vial air bubble (i.e., an unintended blank run)
 - Proteins missing
- What if a surgeon prepared 20 clinical tissue samples, but one originated from a neighboring tissue
 - Proteins have a distinct pattern

Two Recent Articles Describe Robust Transcriptomics Sample Outlier Detection

Abstract

Background: High throughput RNA sequencing is a powerful approach to study gene expression. Due to the complex multiple-steps protocols in data acquisition, extreme deviation of a sample from samples of the same treatment group may occur due to technical variation or true biological differences. The high-dimensionality of the data with few biological replicates make it challenging to accurately detect those samples, and this issue is not well studied in the literature currently. Robust statistics is a family of theories and techniques aim to detect the outliers by first fitting the majority of the data and then flagging data points that deviate from it. Robust statistics have been widely used in multivariate data analysis for outlier detection in chemometrics and engineering. Here we apply robust statistics on RNA-seq data analysis.

Results: We report the use of two robust principal component analysis (rPCA) methods, *PcaHubert* and *PcaGrid*, to detect outlier samples in multiple simulated and real biological RNA-seq data sets with positive control outlier samples. *PcaGrid* achieved 100% sensitivity and 100% specificity in all the tests using positive control outliers with varying degrees of divergence. We applied rPCA methods and classical principal component analysis (cPCA) on an RNA-Seq data set profiling gene expression of the external granule layer in the cerebellum of control and conditional *SnoN* knockout mice. Both rPCA methods detected the same two outlier samples but cPCA failed to detect any. We performed differentially expressed gene detection before and after outlier removal as well as with and without batch effect modeling. We validated gene expression changes using quantitative reverse transcription PCR and used the result as reference to compare the performance of eight different data

Abstract: One of the main problems in the analysis of real data is often related to the presence of anomalies. Namely, anomalous cases can both spoil the resulting analysis and contain valuable information at the same time. In both cases, the ability to detect these occurrences is very important. In the biomedical field, a correct identification of outliers could allow the development of new biological hypotheses that are not considered when looking at experimental biological data. In this work, we address the problem of detecting outliers in gene expression data, focusing on microarray analysis. We propose an ensemble approach for detecting anomalies in gene expression matrices based on the use of Hierarchical Clustering and Robust Principal Component Analysis, which allows us to derive a novel pseudo-mathematical classification of anomalies.

Keywords: anomaly; low rank decomposition; gene expression; clustering; outliers

1. Introduction

Real datasets often contain observations that behave differently from the majority of the data. If an occurrence differs from the dominant part of the data, or if it is sufficiently unlikely under the assumed data probability model, it is considered an anomaly or outlier.

but no software tool had been developed for omics scientists

EnsMOD: A Software Program for Omics Sample Outlier Detection

The screenshot shows the GitHub repository page for EnsMOD. The repository is public and has 92 commits. The repository description is: "EnsMOD: A Software Program for Omics Sample Outlier Detection". It includes sections for About, Releases, Packages, Contributors, and Languages. The Languages section shows HTML at 99.8% and Other at 0.2%.

<https://github.com/niaid/EnsMOD>

Using EnsMOD

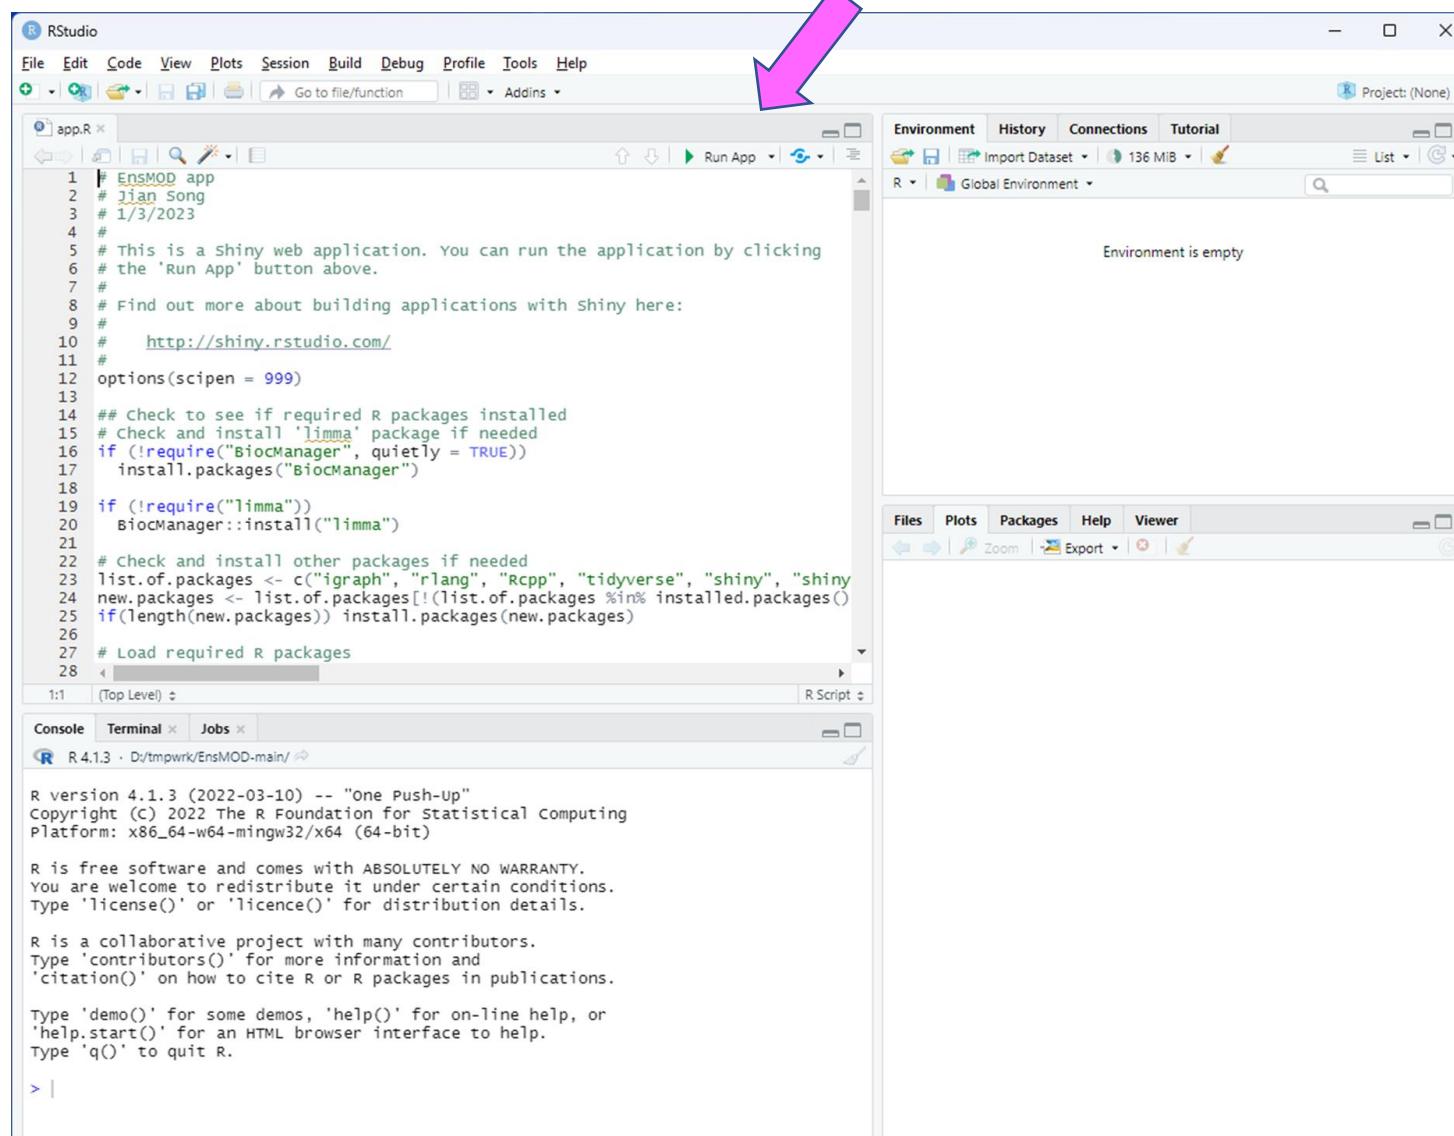

1. Install R from <https://www.r-project.org/>
2. Install RStudio from <https://www.rstudio.com/>
3. Download and unzip EnsMOD: <https://github.com/niaid/EnsMOD>

Using EnsMOD

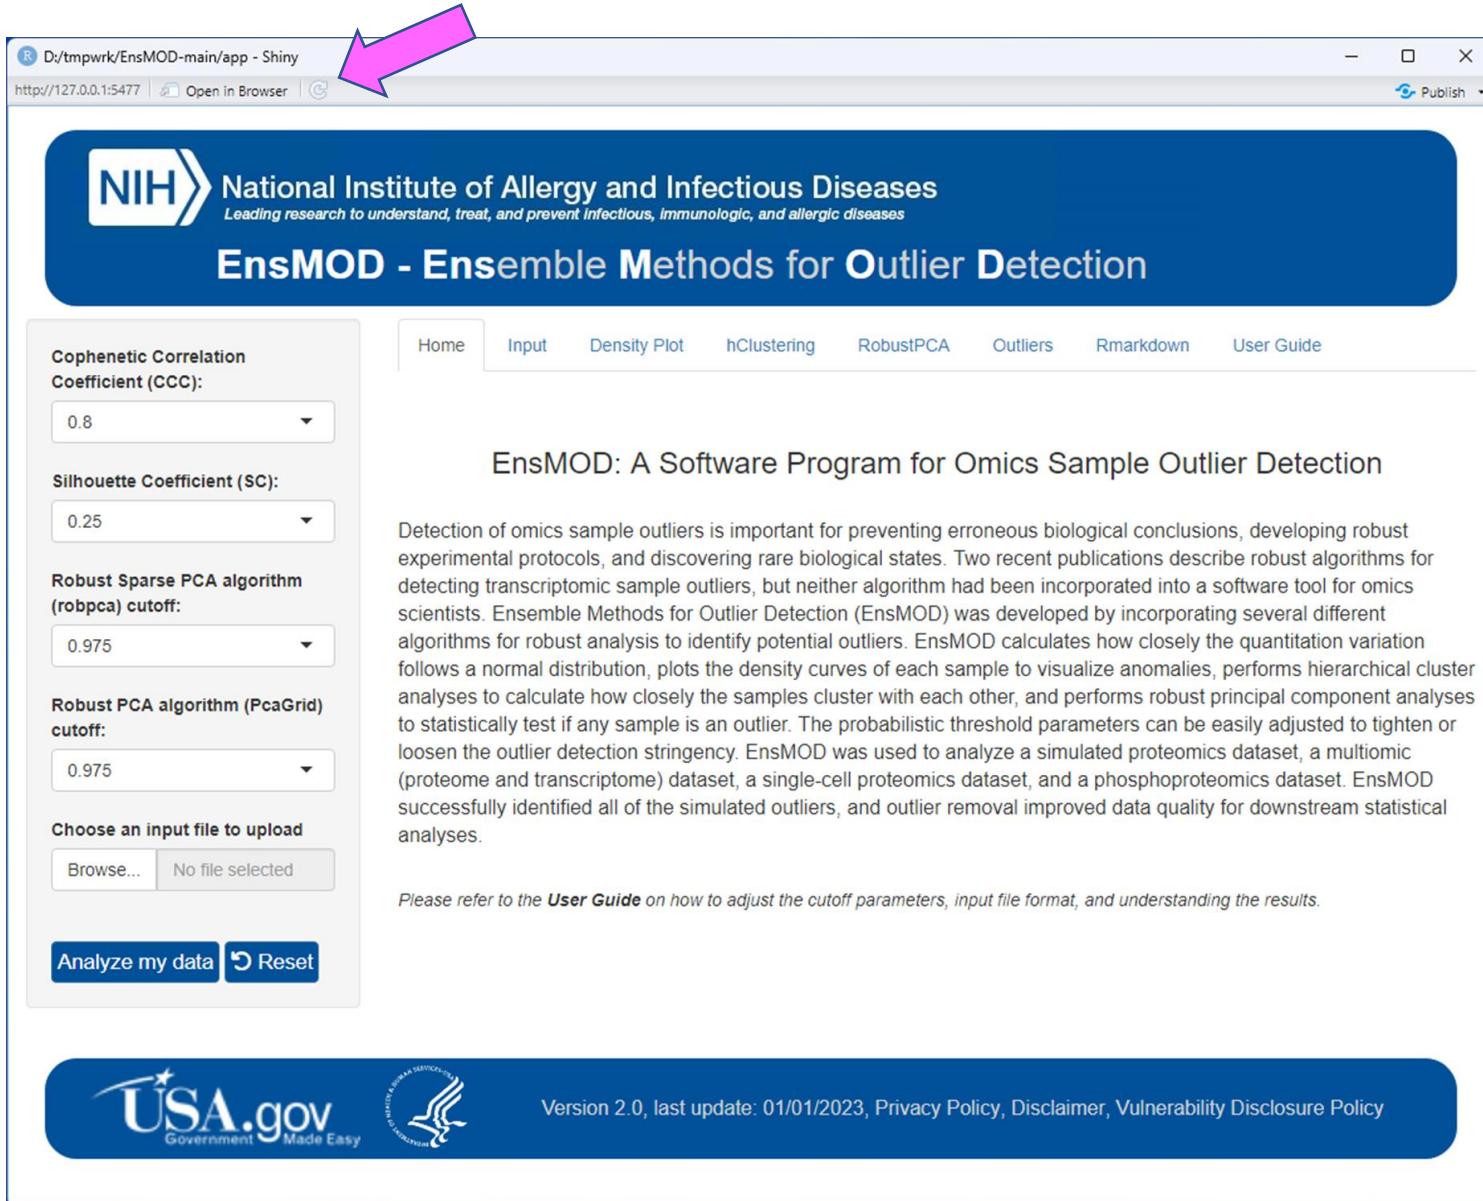

4. Run RStudio and open `/app/app.R`

5. Click “Run App”

Using EnsMOD

6. Click “Open in Browser” (optional)

The screenshot shows the EnsMOD Shiny application running in a web browser. The title bar indicates the path is D:/tmpwrk/EnsMOD-main/app - Shiny and the URL is http://127.0.0.1:5477. A pink arrow points to the "Open in Browser" button in the top left corner of the browser window.

Using EnsMOD

EnsMOD HTML Output File of all Results is in \app\www\EnsMODoutputs\

The screenshot shows a web browser window with the title "Ensemble_Methods_for_Outlier_Detection_v2_0.html". The page content is as follows:

Ensemble_Methods_for_Outlier_Detection_Version_2.0

16 May, 2023

- 1. Set the Statistical Parameters and Prepare and Visualize the Input Data
- 2. Hierarchical Clustering for the Cophenetic Correlation Coefficient
- 3. Hierarchical Clustering for the Silhouette Coefficients
- 4. Robust PCA
 - 4.1 Robust Sparse PCA algorithm (robPCA)
 - 4.2 Robust PCA based on Projection Pursuit (PP) using GRID (PcaGrid)
- 5. Summary of the Results and Identification of Outlier(s)
 - 5.1 Outlier(s) Identified by Robust PCA analyses
 - 5.2 Outlier(s) Identified by Hierarchical Clustering
 - 5.3 Outlier(s) Identified by Both HCA and Robust PCA
- 6. References

1. Set the Statistical Parameters and Prepare and Visualize the Input Data

The four statistical cutoff values are set below. Your input file is loaded in here. The data are filtered by removing any row with "NaN" (missing values). Density plots are used to visualize the distribution of gene/protein expression values within each sample and across the samples. The normality of the dataset is visualized and tested. Note that it is unclear how accurately outliers will be detected if the input dataset is significantly different from a normal distribution.

```
# Set the Cophenetic Correlation Coefficient (CCC) cutoff (higher is more stringent).
# The CCC is a measure of how faithfully a dendrogram preserves the pairwise distances
# between the original unmodeled data points.
CCC_min <- as.numeric(params$CCC_min)
CCC_min
```

```
## [1] 0.8
```

```
# Set the Silhouette Coefficient (SC) cutoff (Lower is more stringent).
# The SC is a measure of how similar an object is to its own cluster (cohesion) compared to other clusters (separation).
SC_max <- as.numeric(params$SC_max)
SC_max
```

```
## [1] 0.25
```

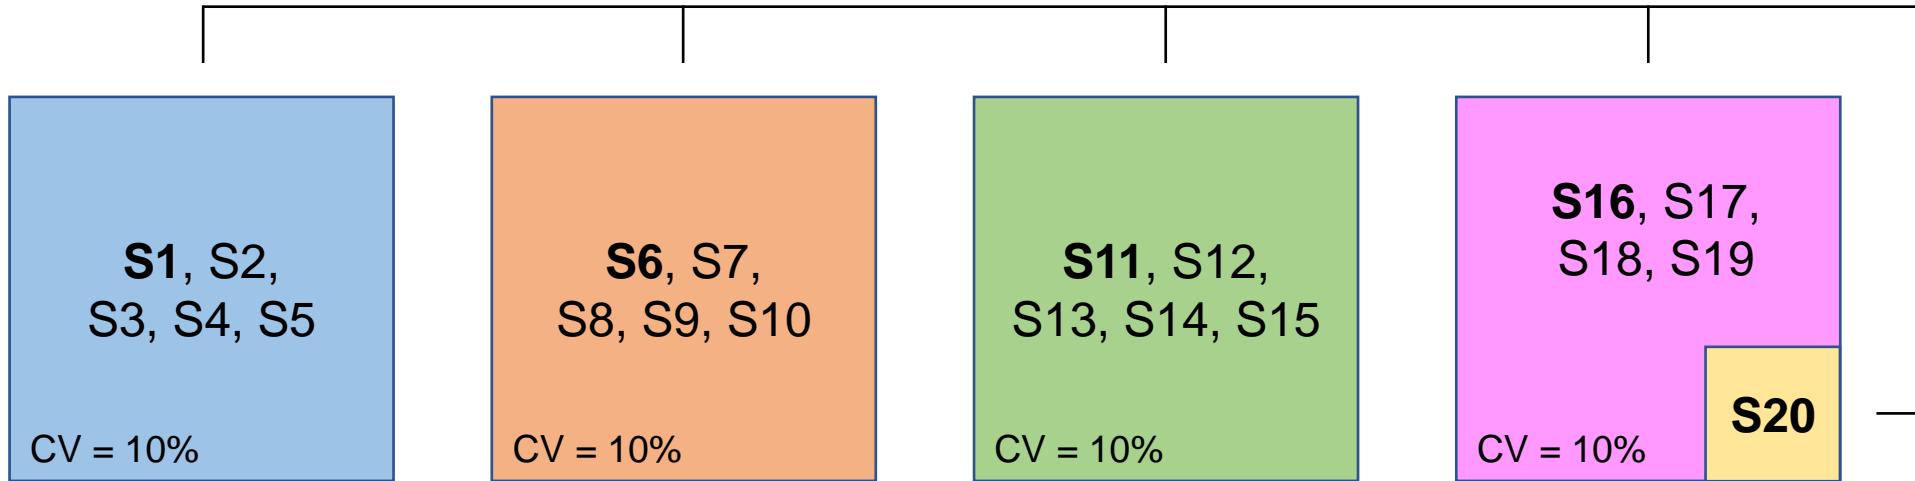

```
# Set the Robust PCA algorithm (robPCA) cutoff (higher is more stringent).
# For normally distributed data, this value is the estimated fraction of the samples that are not falsely classified as outliers.
robPCA_prob <- as.numeric(params$robPCA_prob)
robPCA_prob
```

```
## [1] 0.999
```

Simulated Proteomics Dataset

Simulated Proteomics Dataset

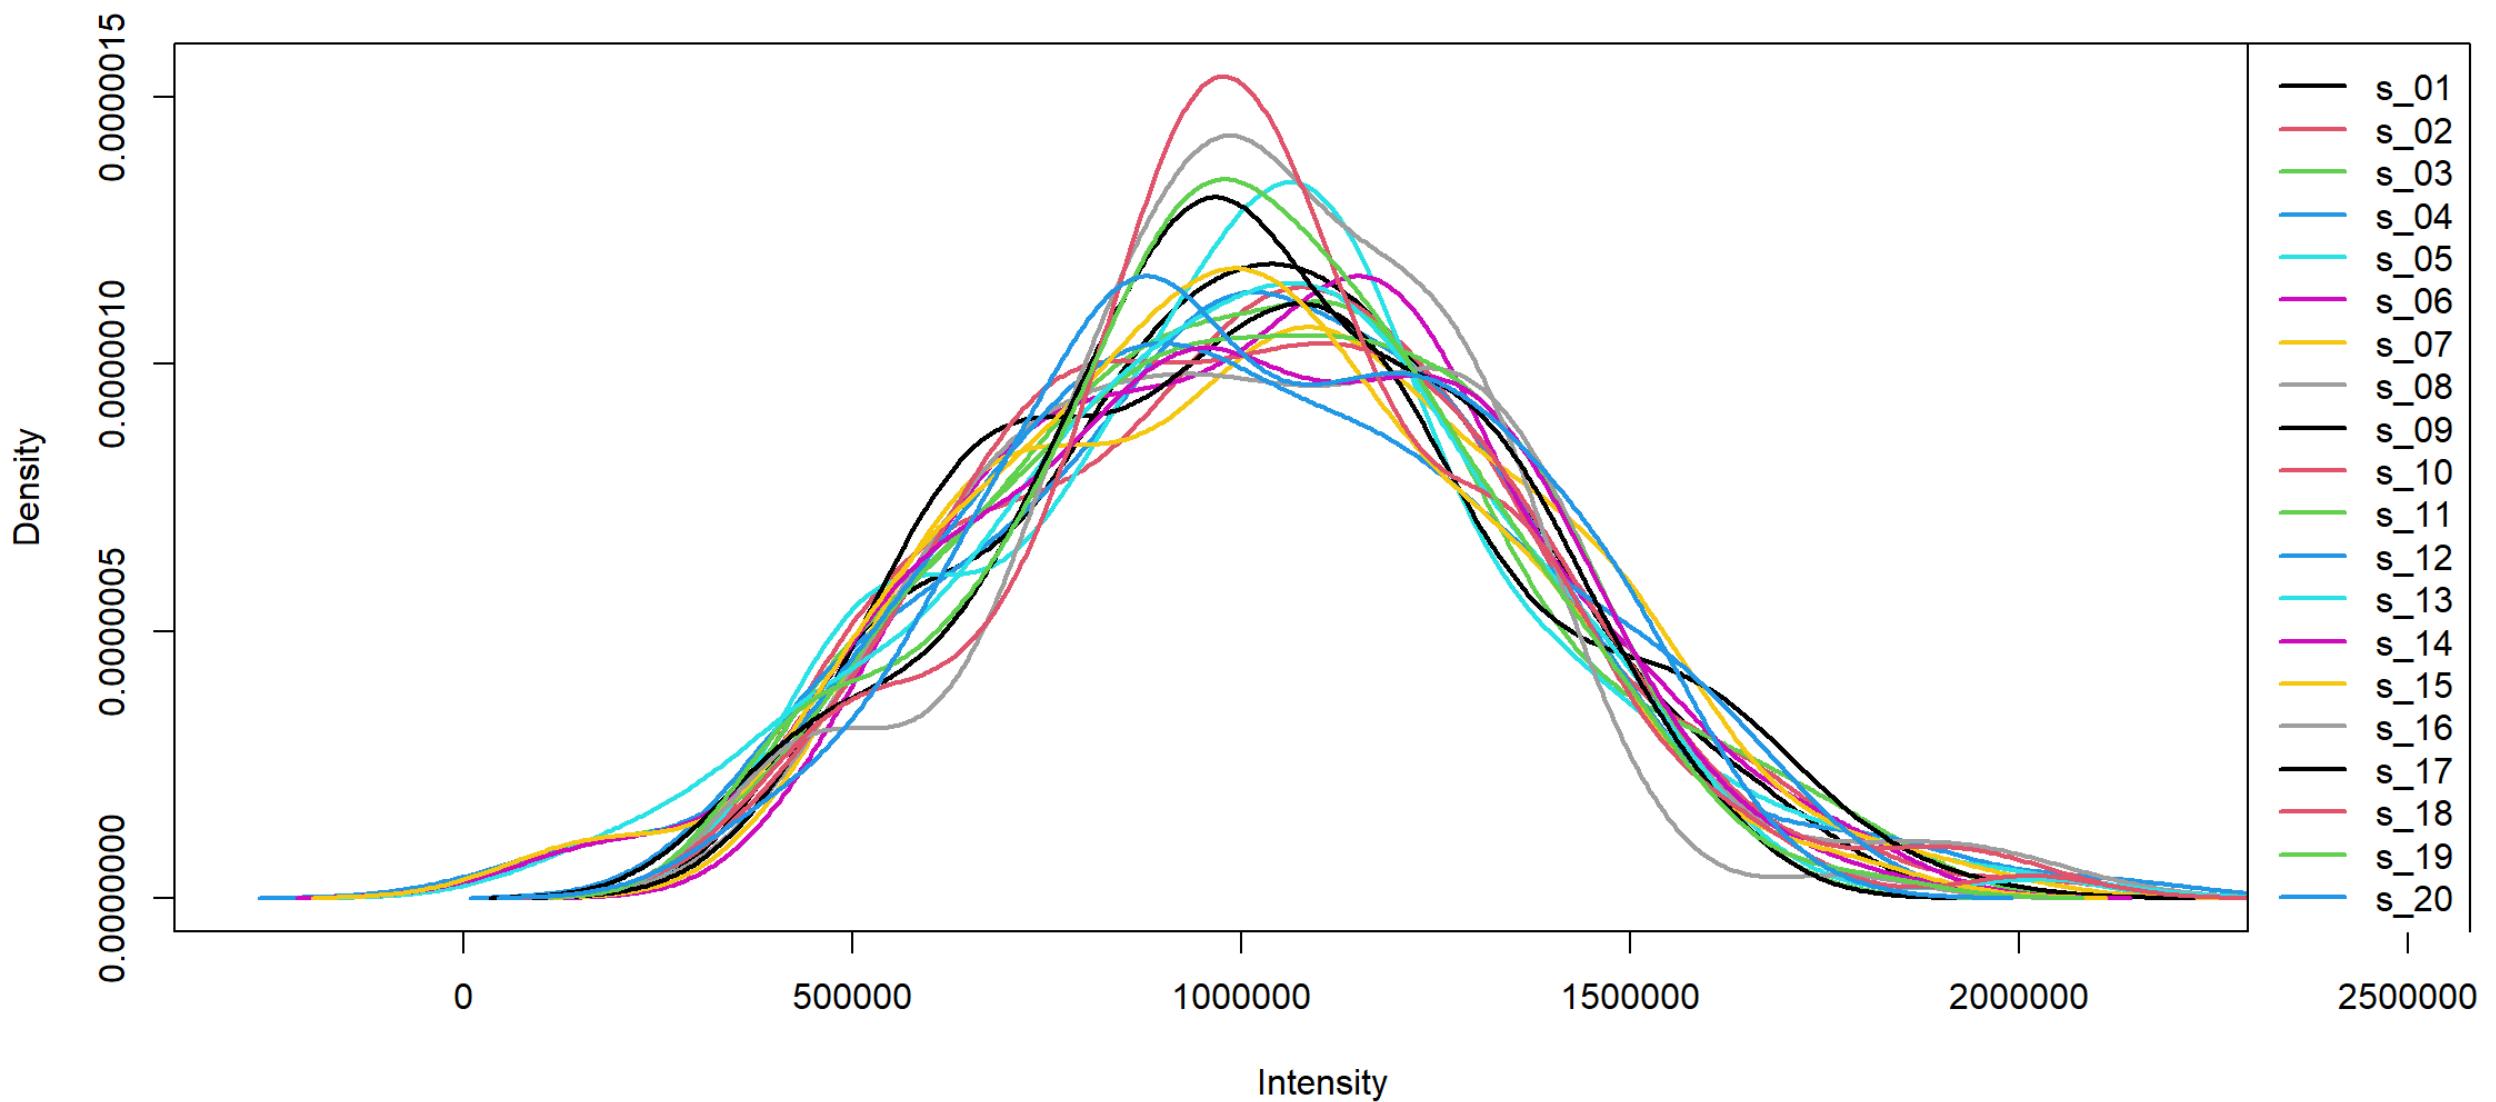

Coefficient of Variation (CV) = 30%

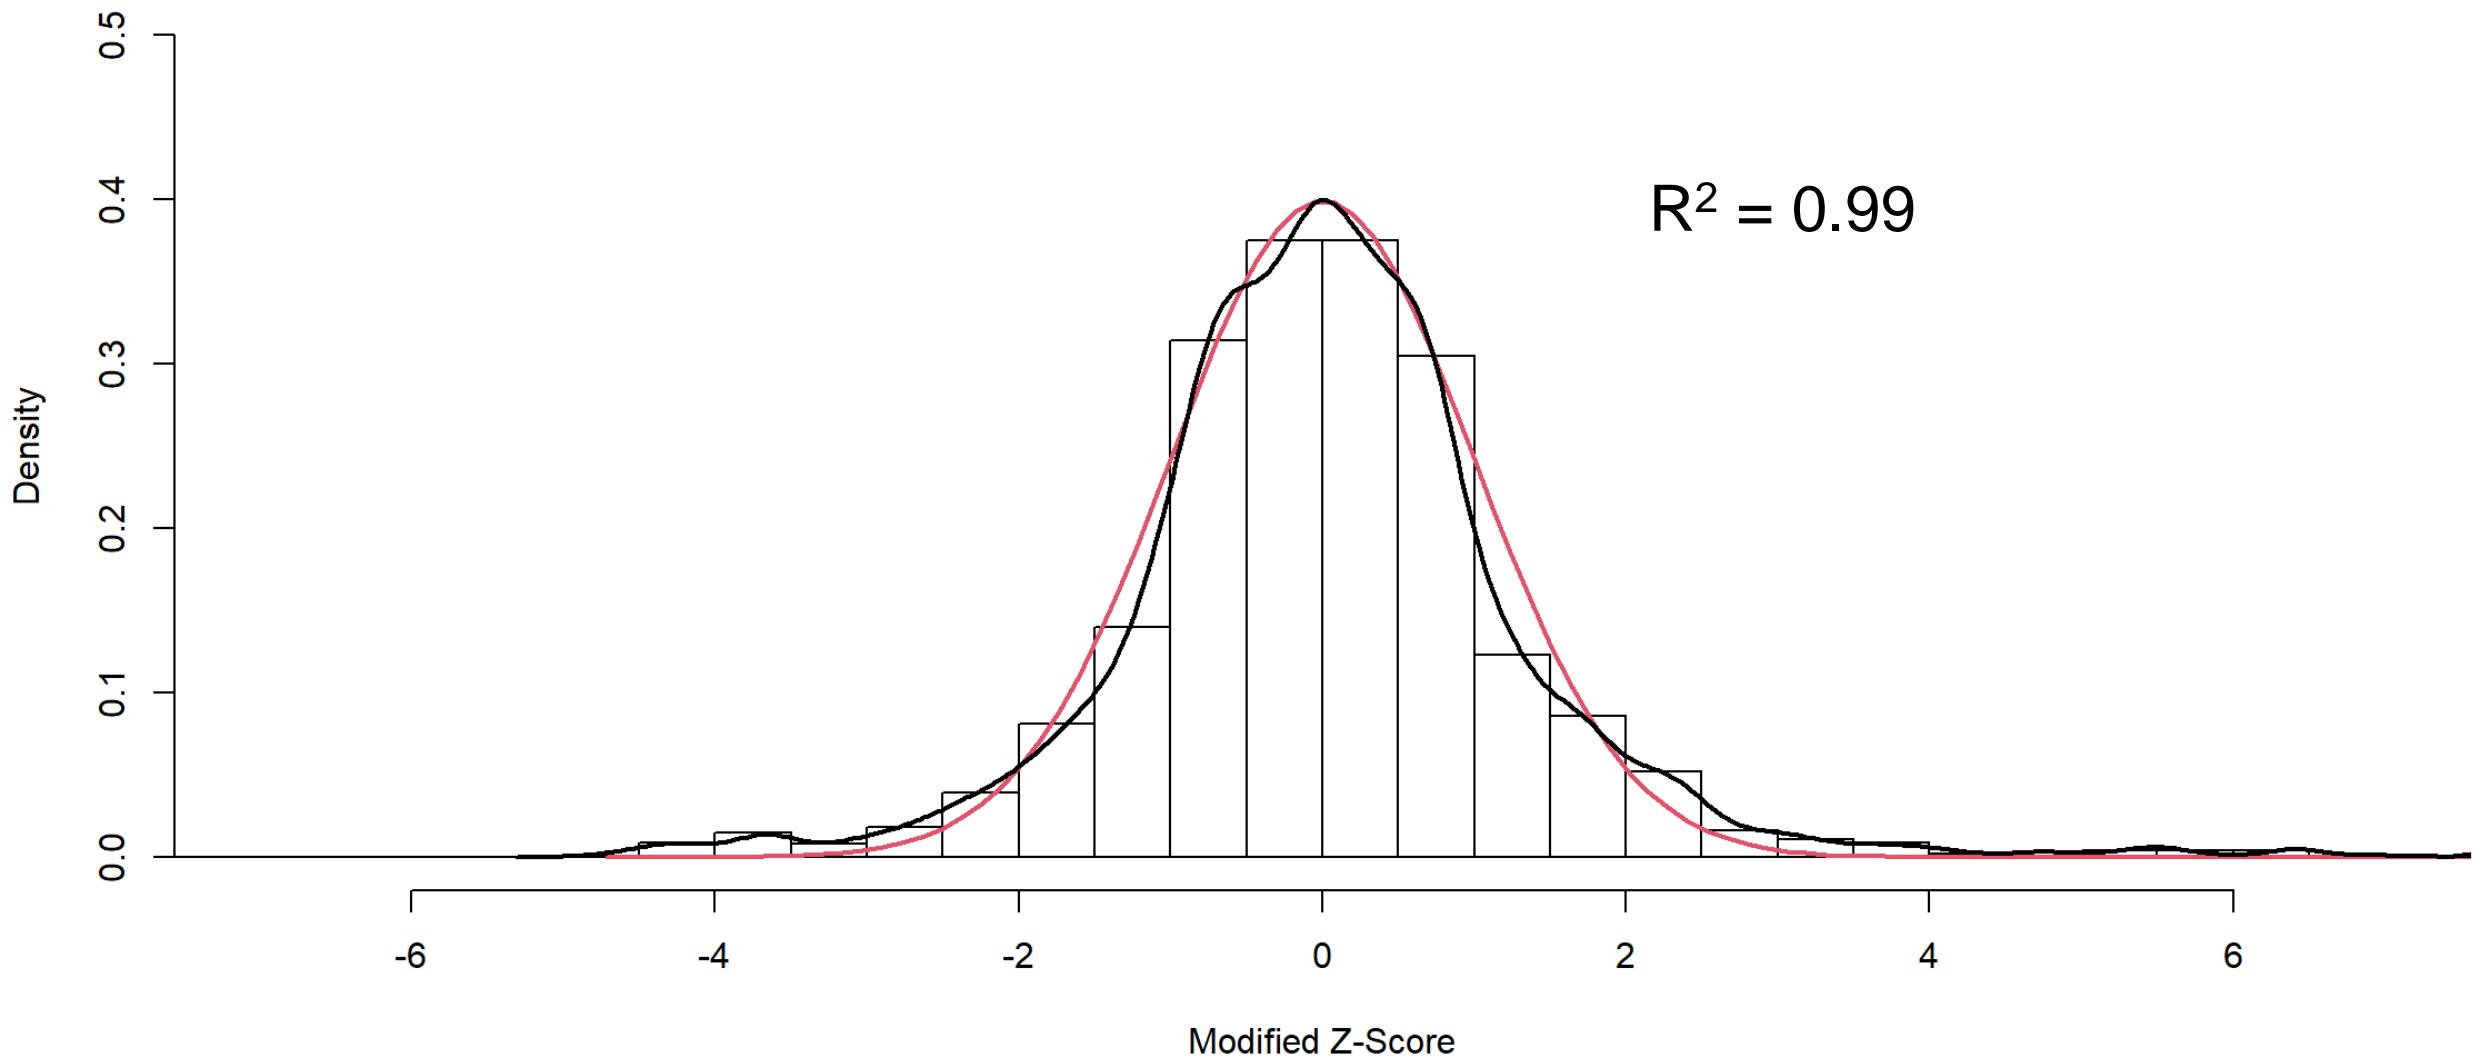

S1, S6, S11, S16, S20 = Initial Gaussian random sampling

$\mu = 1,000,000$, CV = 30%, N=100 proteins

Densities of the Abundance Values for each Sample

Empirical Histogram and Density versus the Standard Normal Distribution

Hierarchical Cluster Analyses and the Cophenetic Correlation Coefficient (CCC)

3 Distances: Euclidean, Manhattan, Pearson Correlation

5 Linkages: Single, Average, Complete, Centroid, Ward

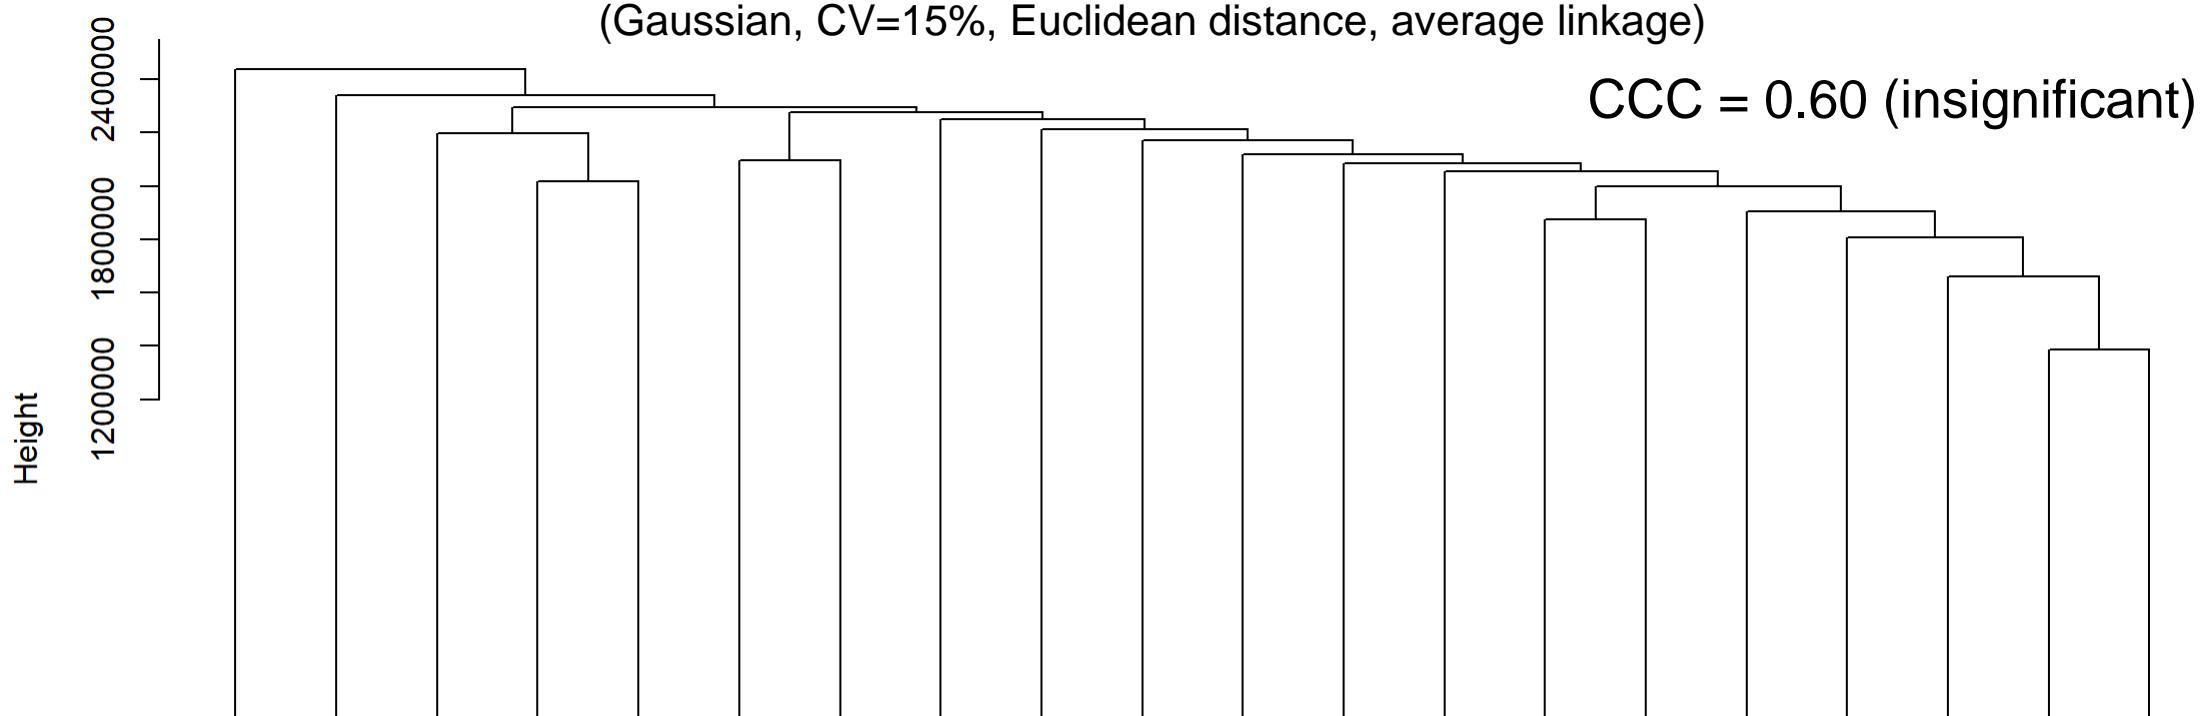

$3 \times 5 = 15$ HCAs total

The HCA with the largest CCC is selected for downstream analyses

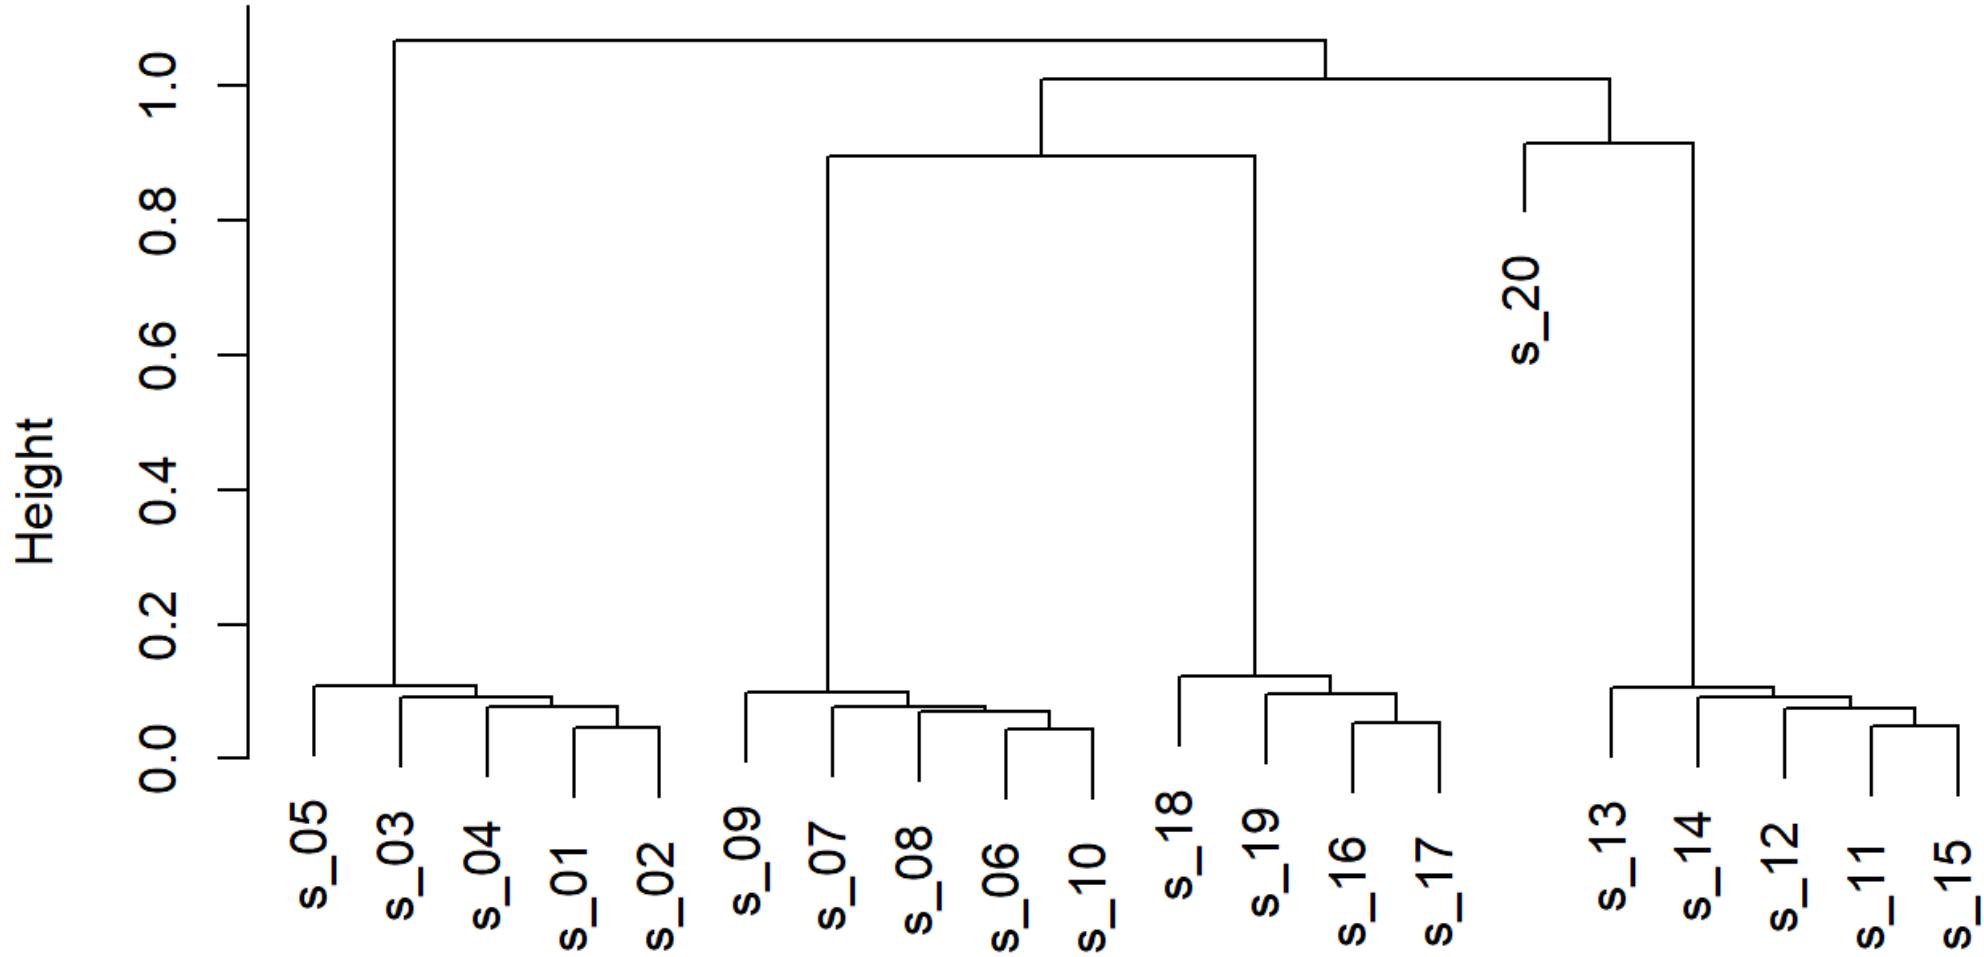

If $\text{CCC} \geq 0.8$, then outliers might be identifiable [Selicato et al 2021 Mathematics 9:882]

Example of poor clustering: HCA of purely random data

(Gaussian, CV=15%, Euclidean distance, average linkage)

If CCC ≥ 0.8 (default parameter value), then outliers might be identifiable

CCC = 0.99 (Pearson corr. distance, avg. linkage)

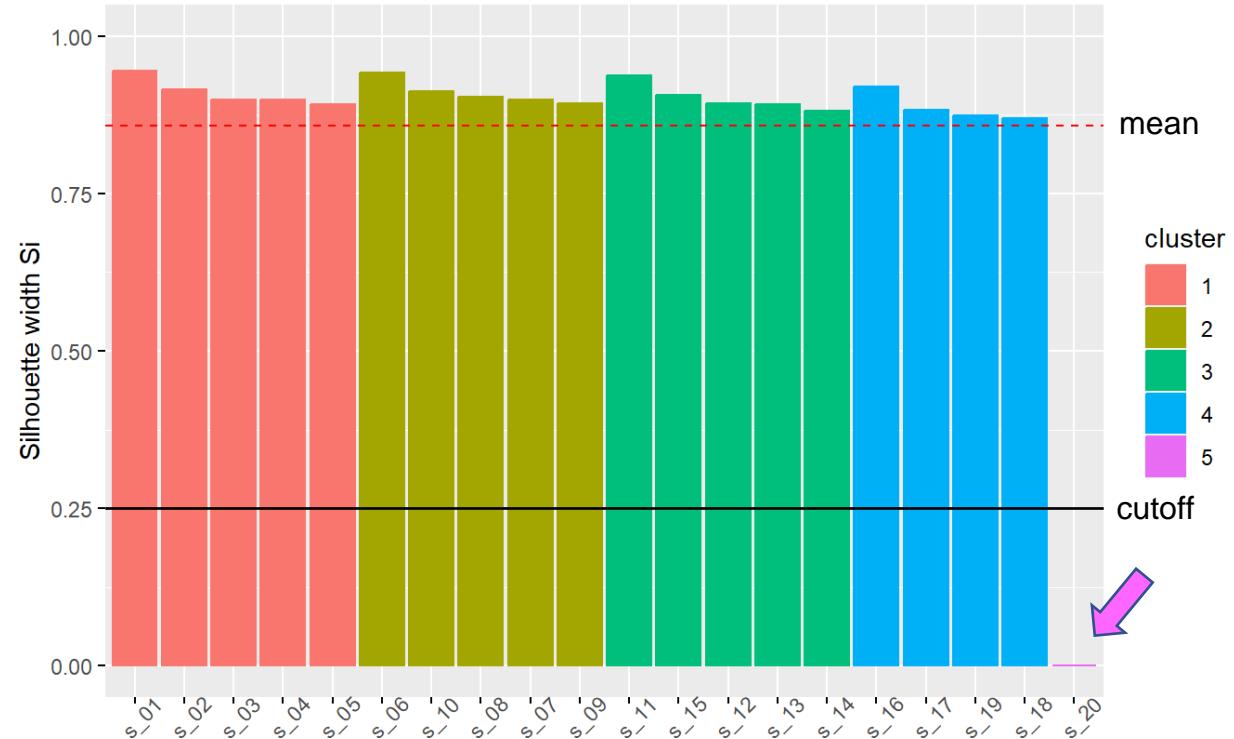

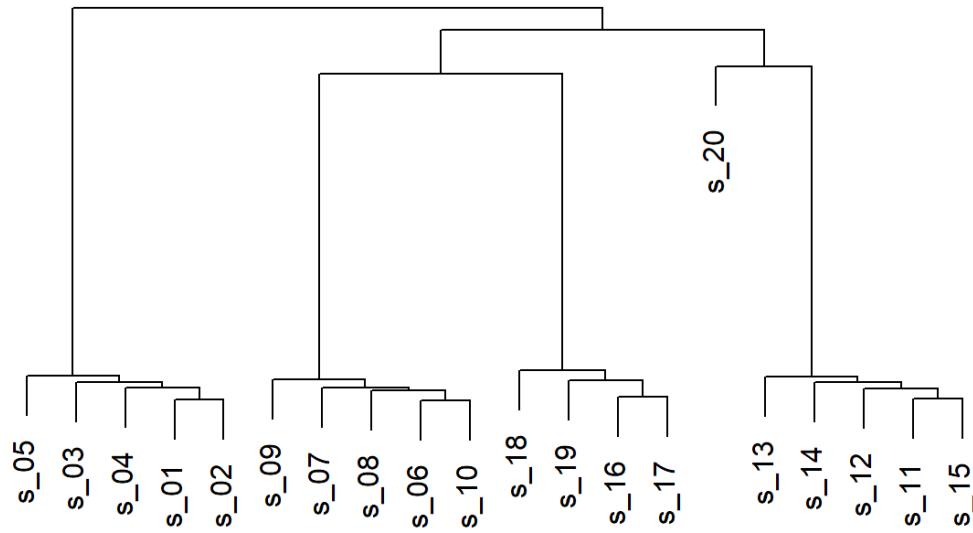

Silhouette Coefficient (SC)

The SC of a sample within an HCA quantifies:
how well the sample fits within its own HCA cluster
versus
how well the sample would fit in the other HCA clusters

Table 1. Structures corresponding to particular Silhouette coefficient ranges.

SC	Interpretation
0.71–1.0	A strong structure was found.
0.51–0.70	A reasonable structure was found.
0.26–0.50	The structure is weak and may be artificial.
<0.25	No substantial structures have been found.

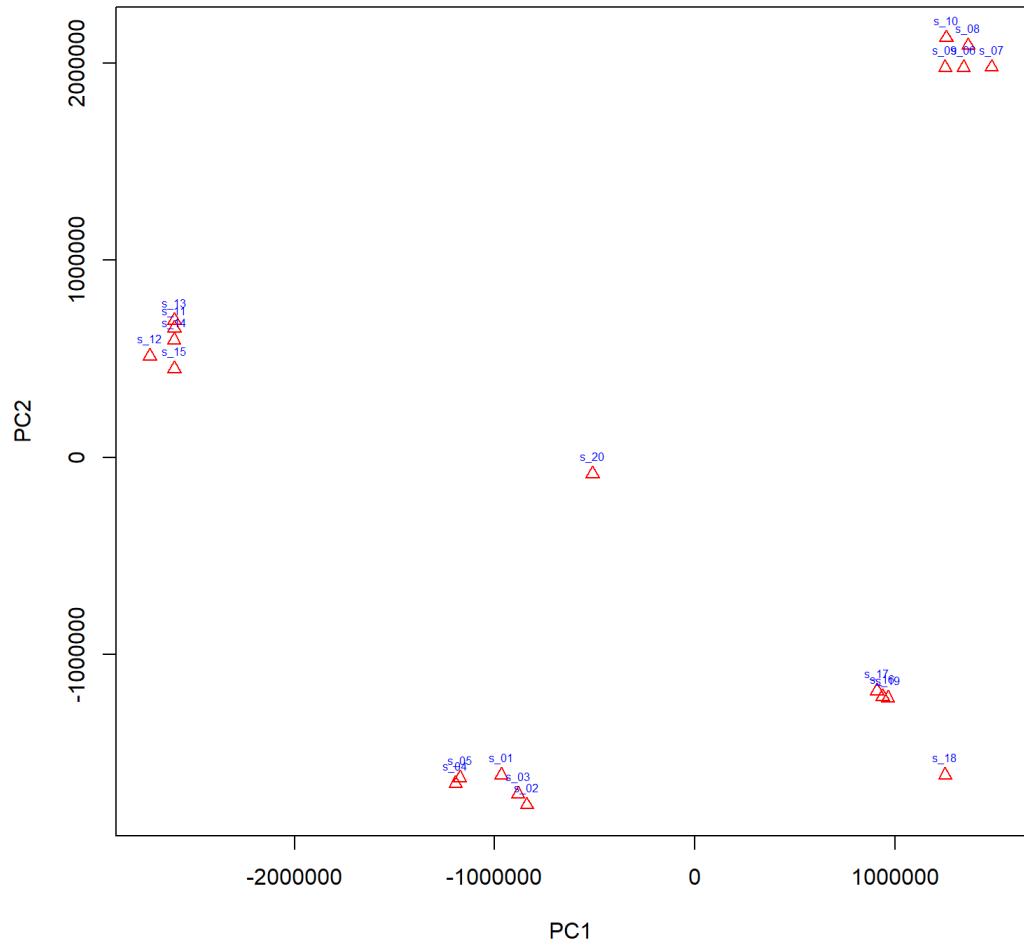

If $SC < 0.25$ (default parameter value), then the sample might be an outlier

$SC[s_{20}] = 0$

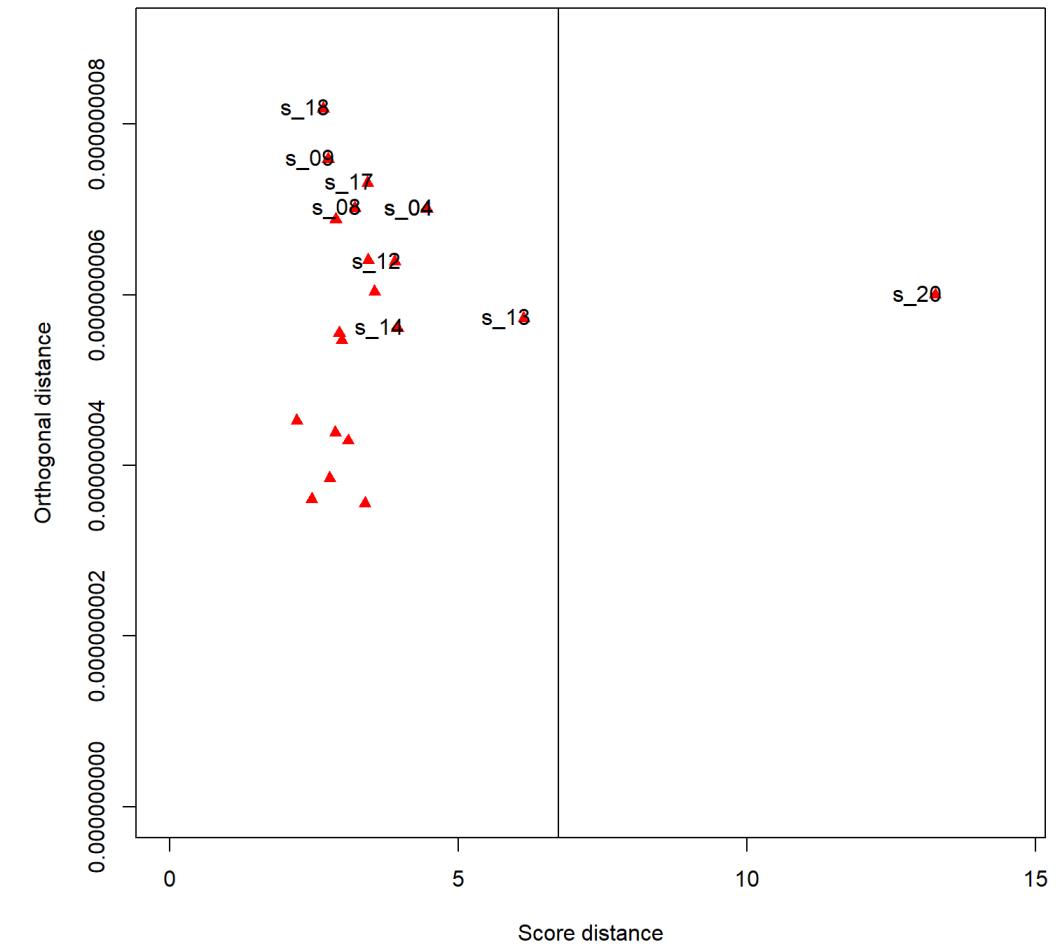

Two Robust Principal Component Analyses are Performed

Robust PCA (PcaGrid) BiPlot

robPCA was also performed (not shown)

Robust PCA (PcaGrid)

PcaGrid parameter was set to 99.9%
Estimated Confidence = $(99.9\%)^2 = 99.8\%$

5.3 Outlier(s) Identified by Both HCA and Robust PCA

```
# The samples that satisfied all four criteria (CCC, SC, robpca, PcaGrid) for an outlier:  
if (CCC_df_ranked_top$CCC >= CCC_min) {  
  intersect(intersect(hcOutliers, rosOutliers), pcOutliers)  
}  
  
## [1] "s_20"
```

Anthrax Phosphoproteomics

Spleen Phosphoproteomics of Mice with Anthrax

Toxin-,
capsule-,
asymptomatic,
abortive infection

Toxin+,
capsule-,
lethal
in 2-4d

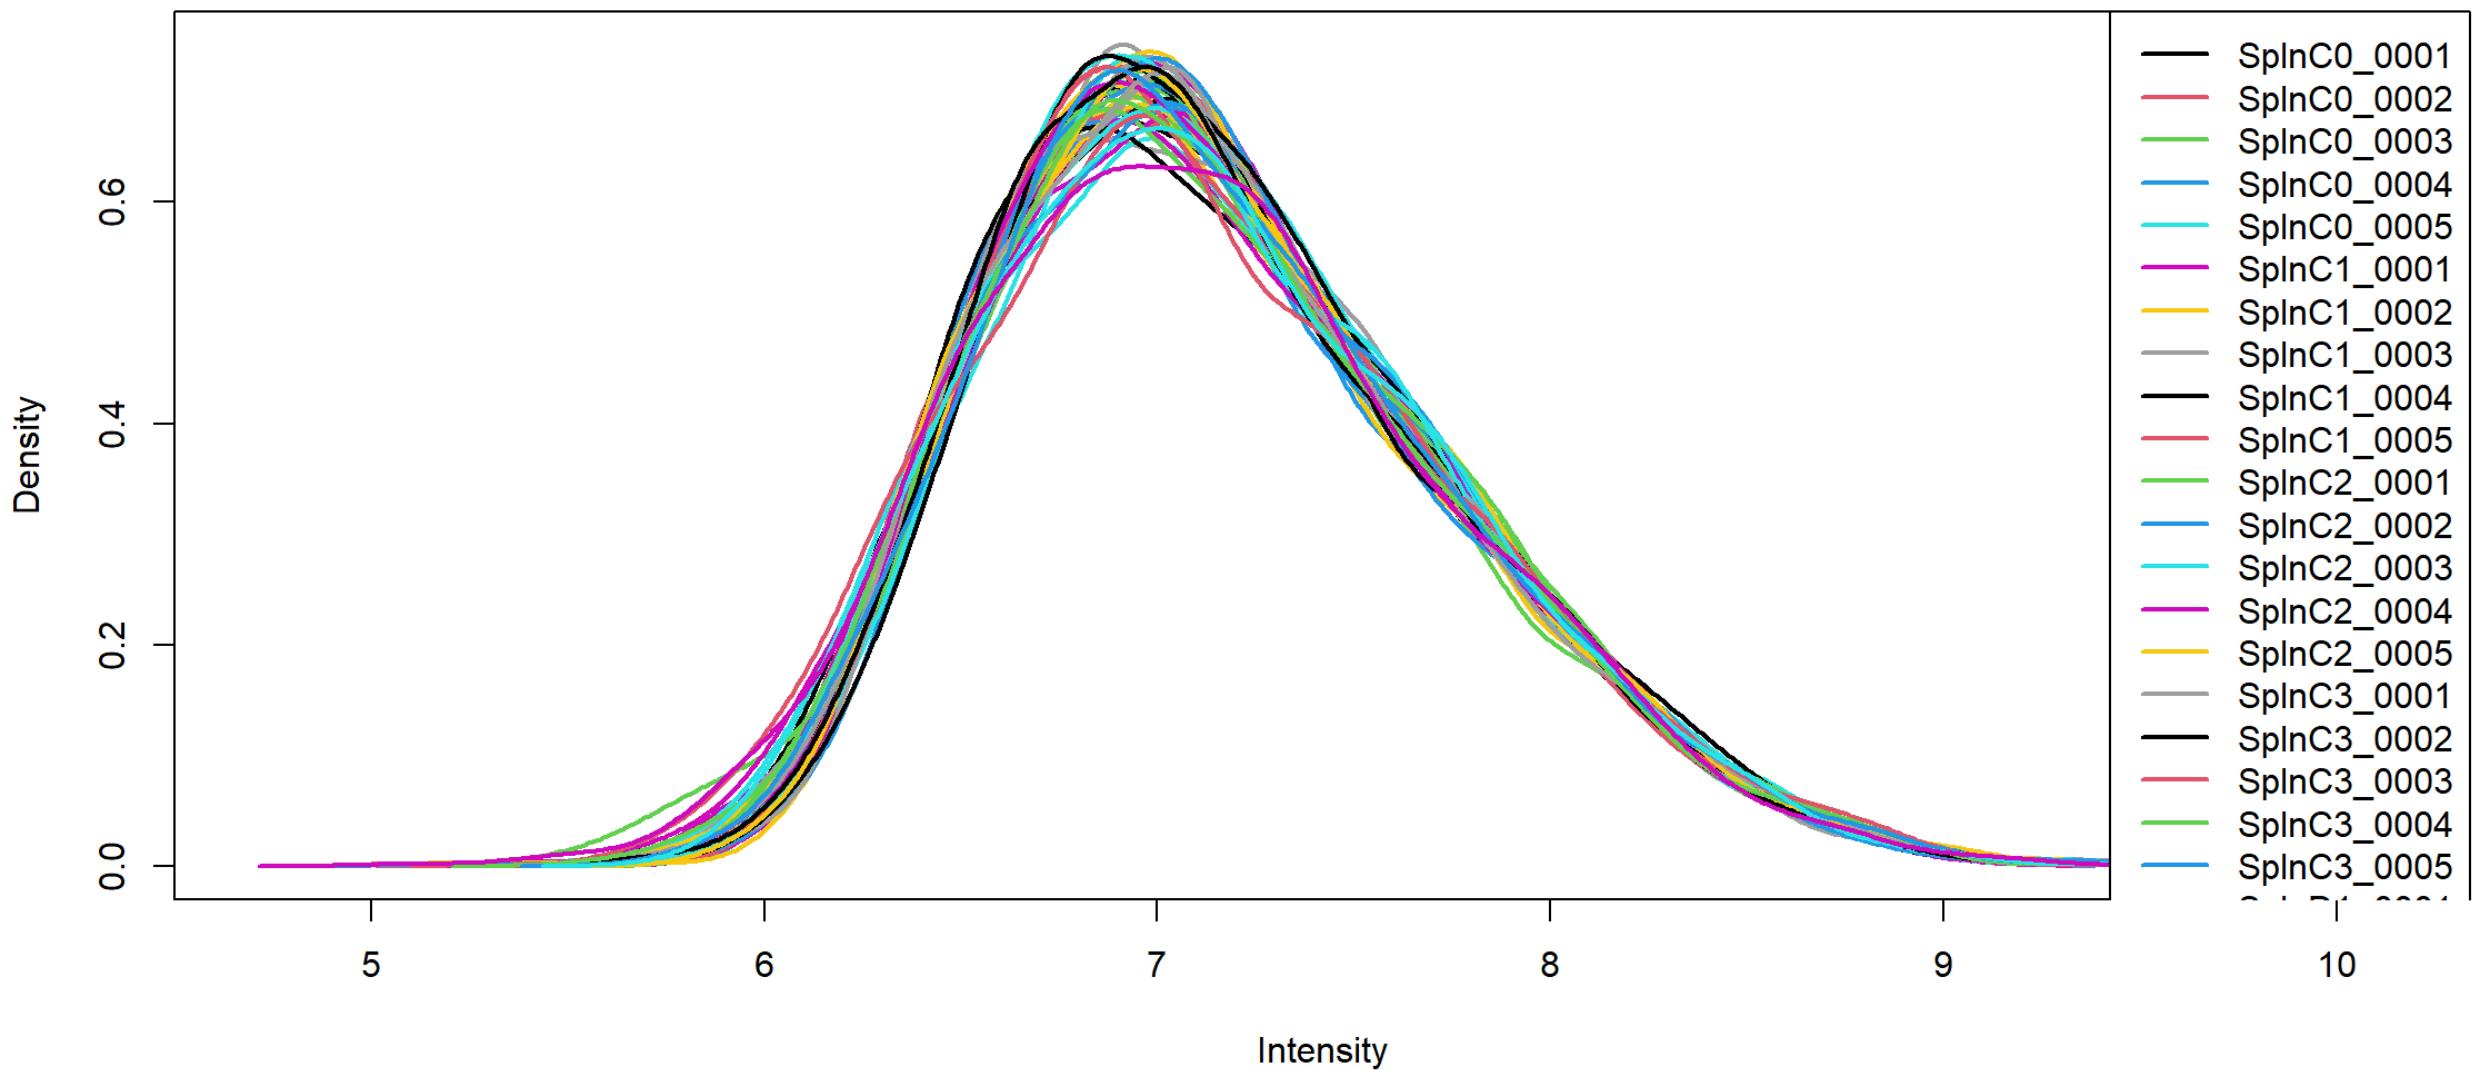

Prepared: 5 mice 15 mice 15 mice 25 mice

Time	No Injection	Vehicle	Δ Sterne	Sterne
0 h	5 mice			
24 h		5 mice	5 mice	5 mice
48 h		5 mice	5 mice	5 mice
72 h		5 mice	5 mice	1 mouse

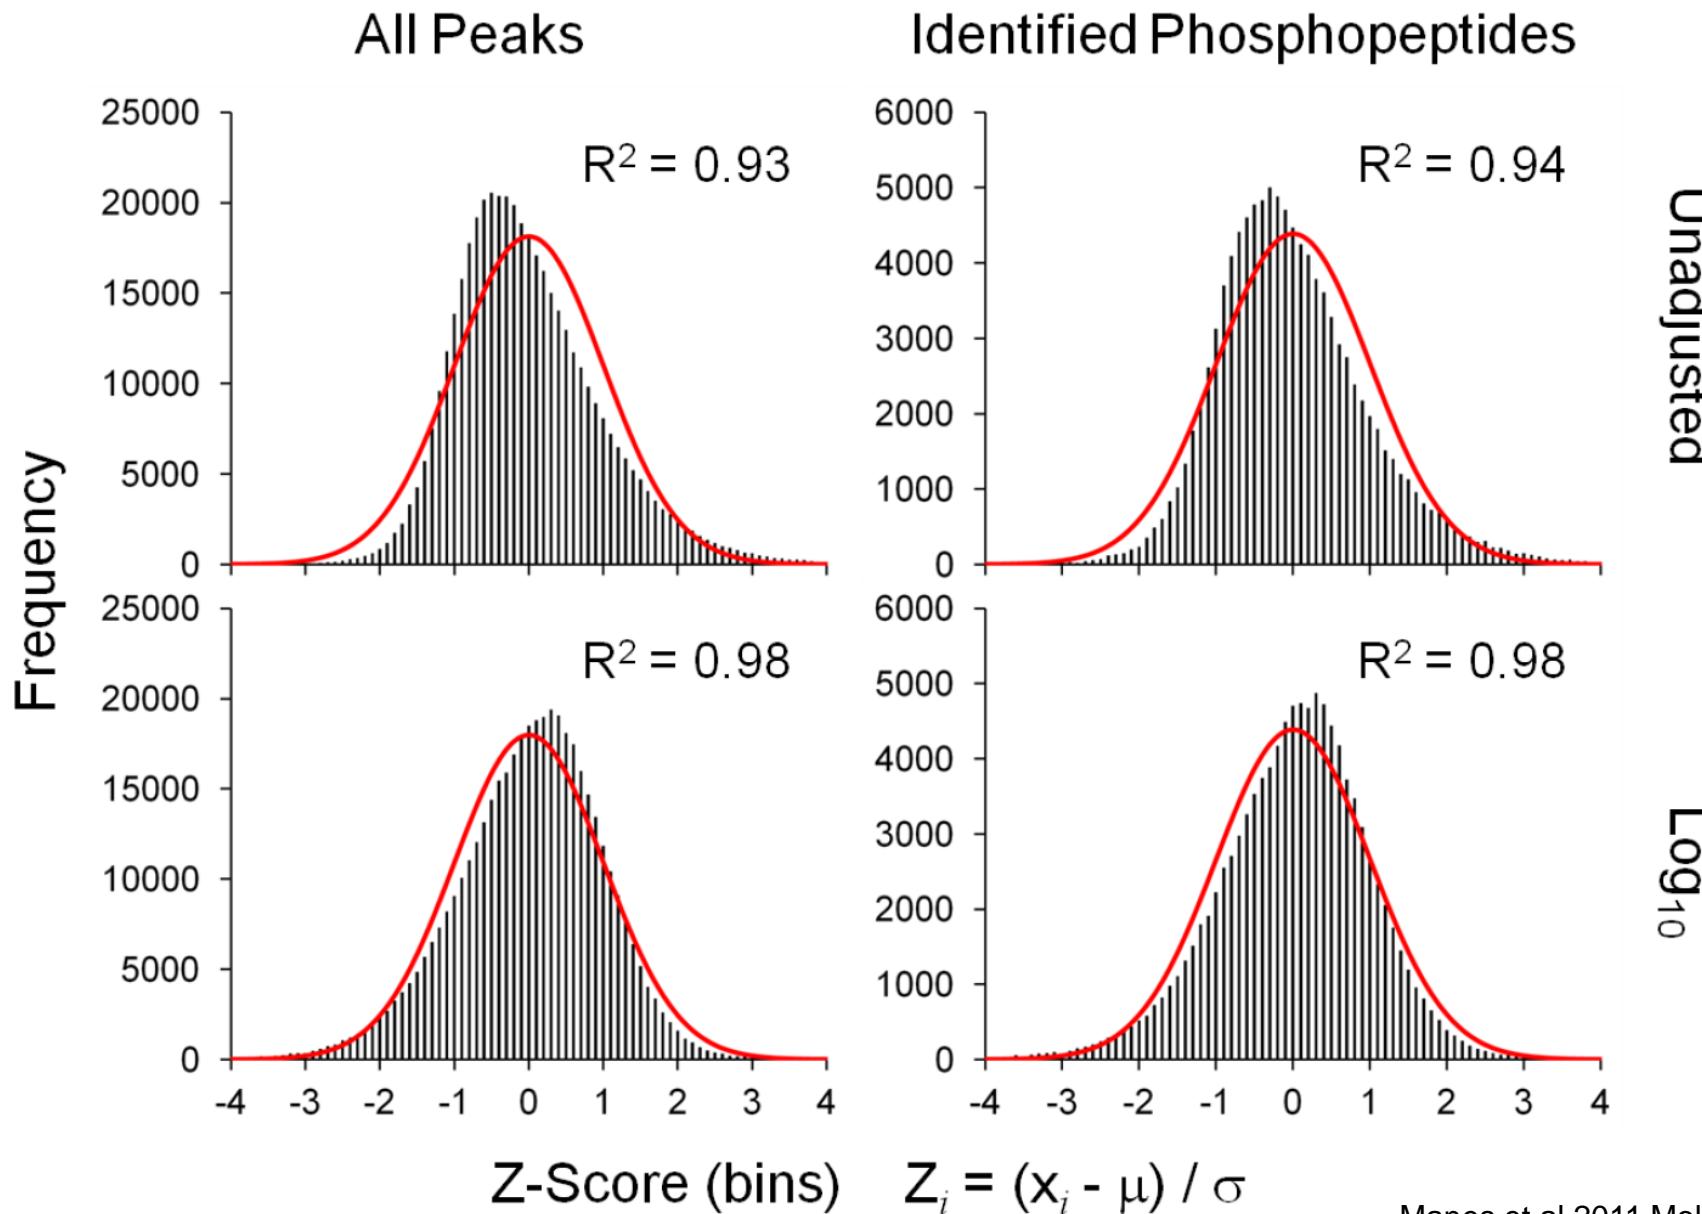

The Sterne 72h sample functioned as a pseudo-outlier

Spleens homogenized, trypsin, phosphopeptides enriched, LC-MS(/MS), label-free quant., Log_{10} -transformed

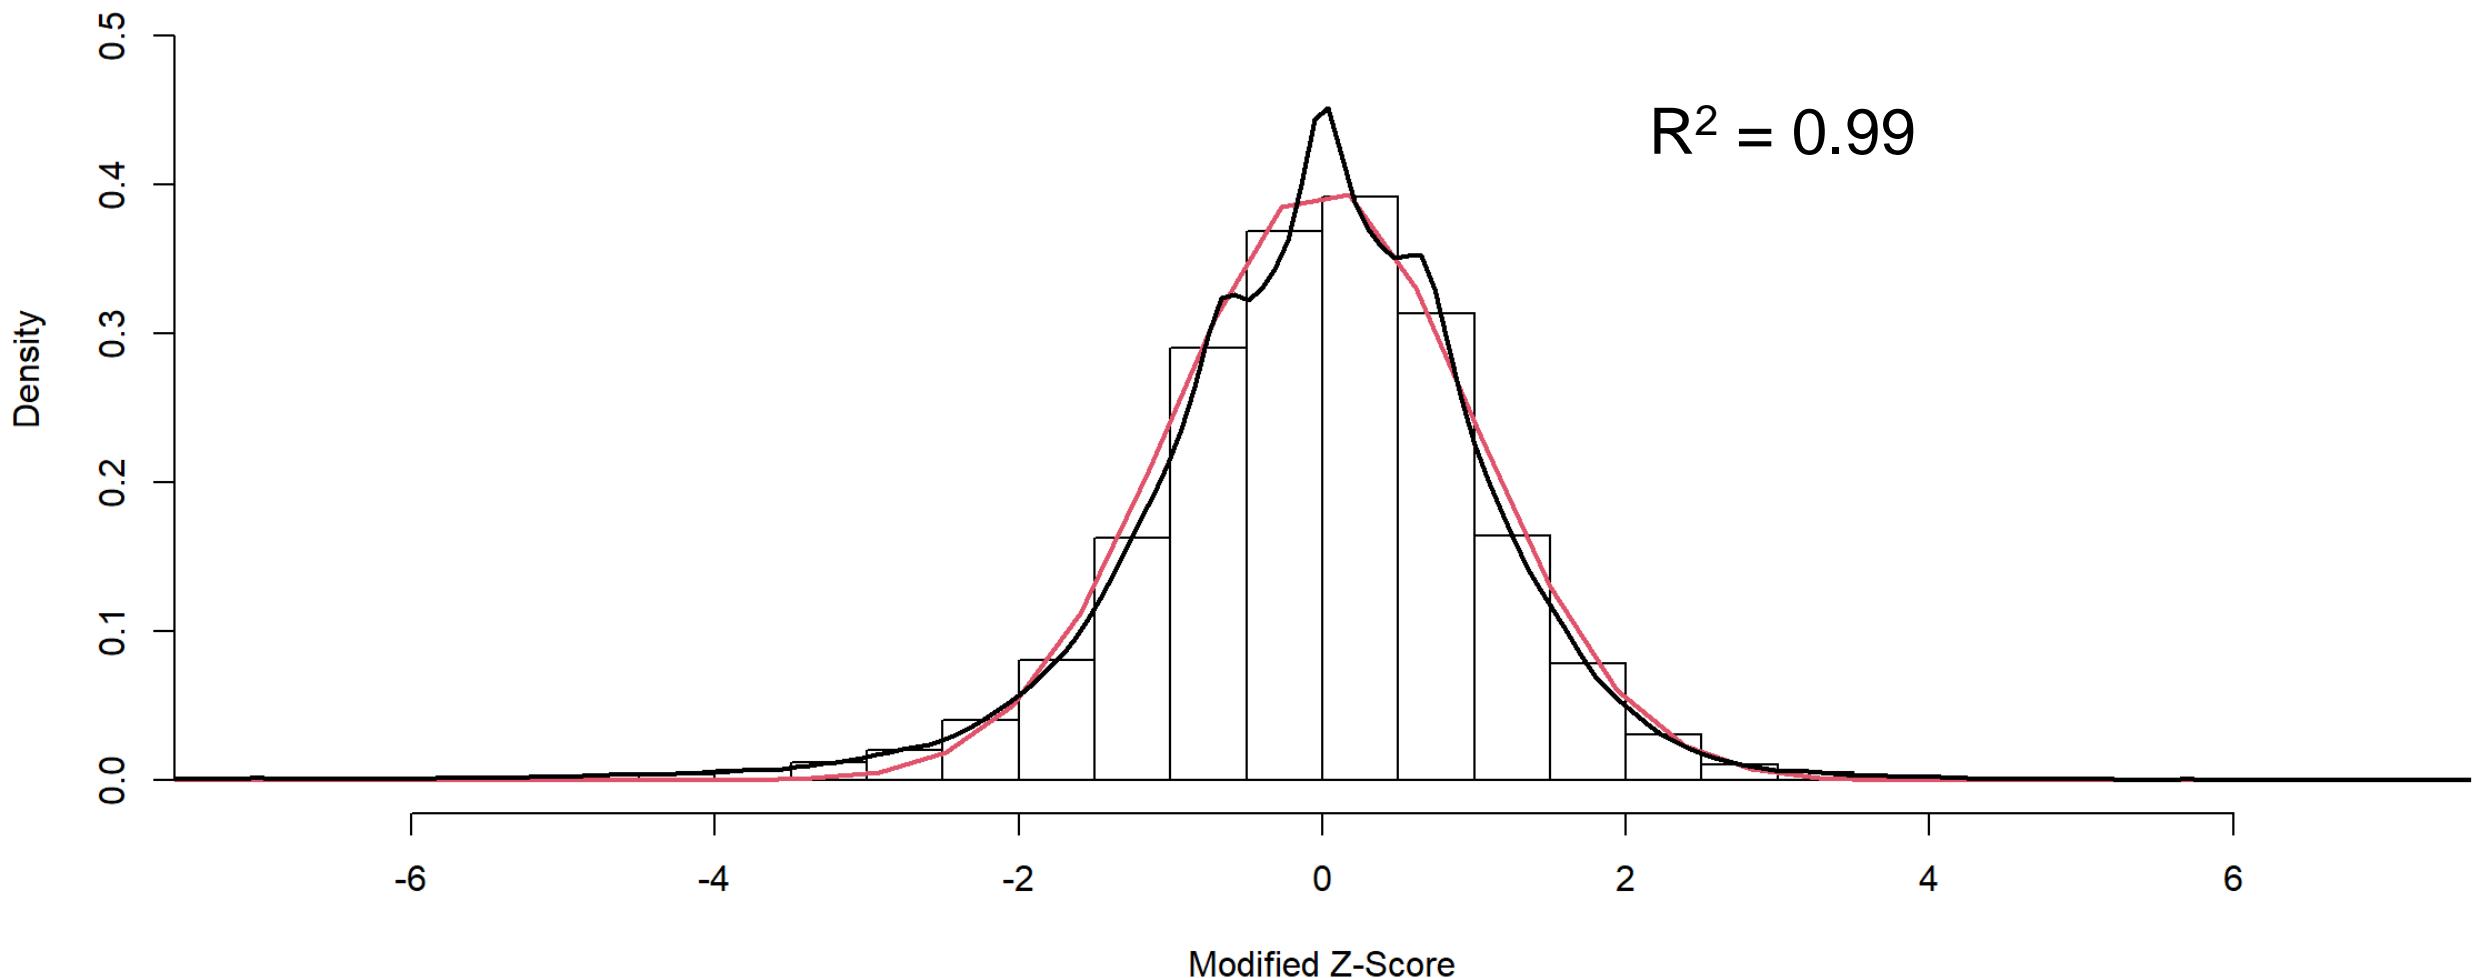

Densities of the Abundance Values for each Sample

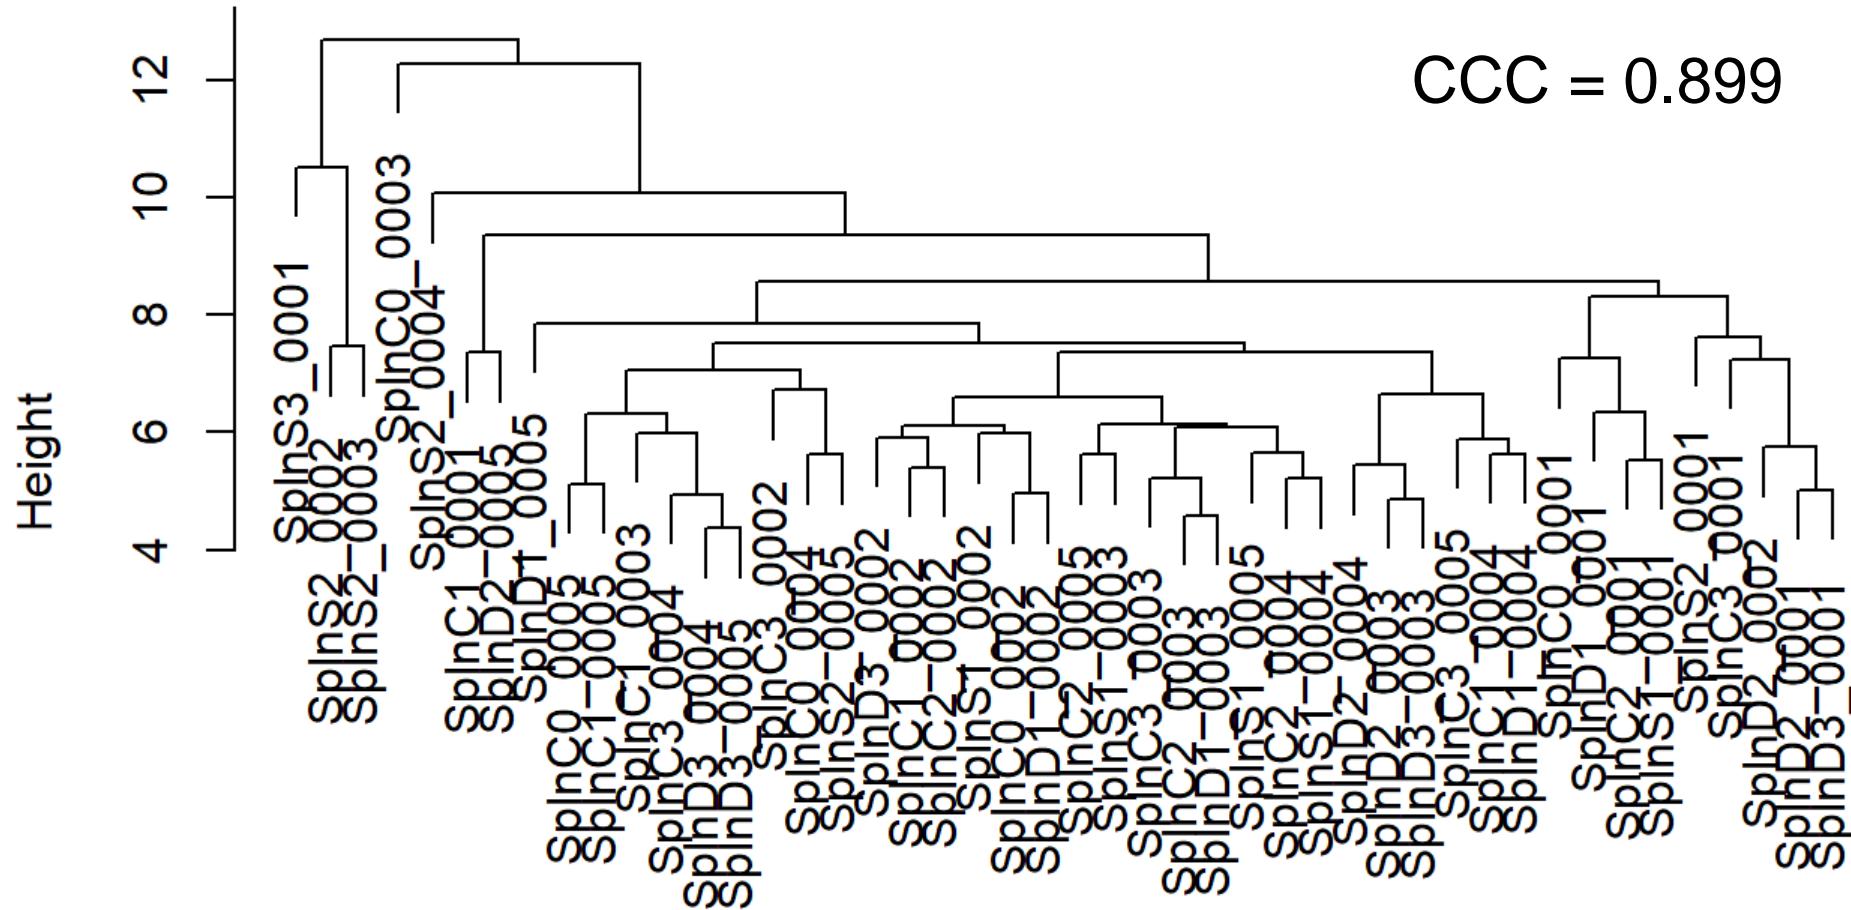

LC-MS Intensity Data are Log-Normal

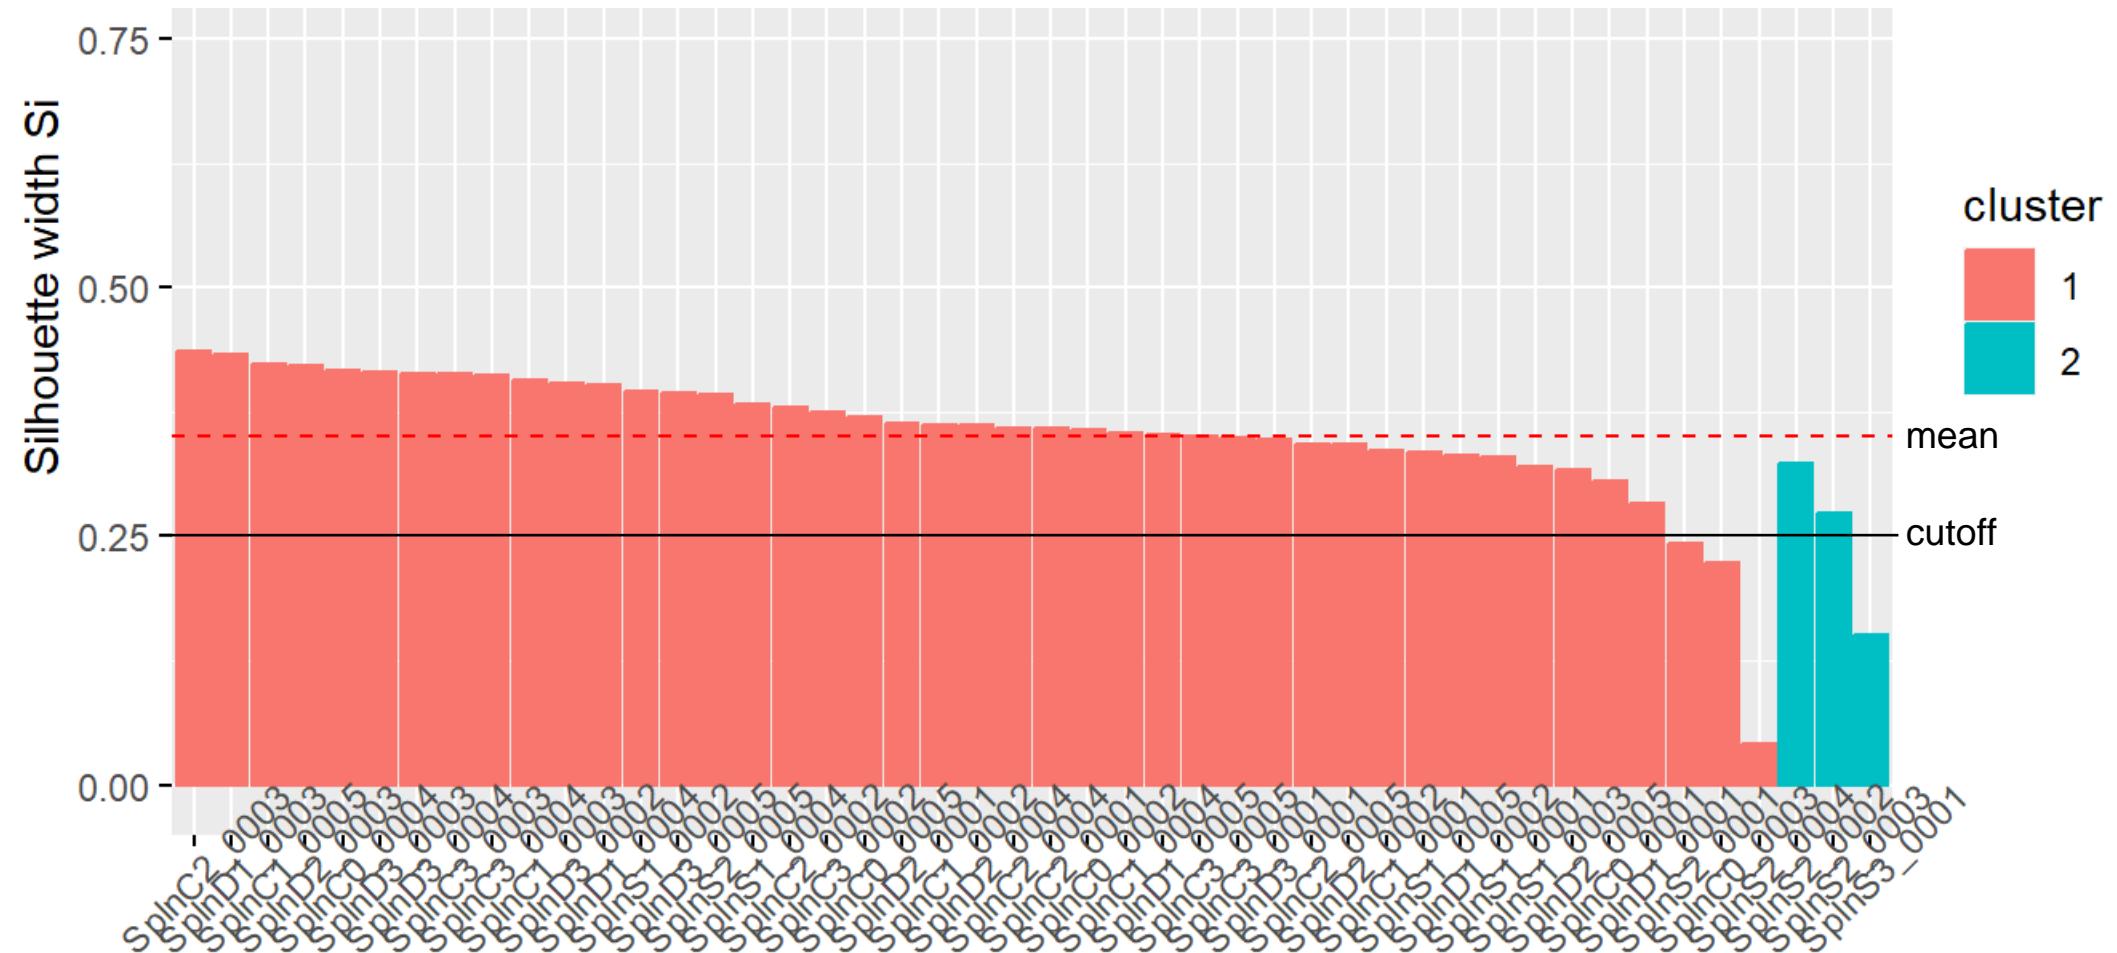

Empirical Histogram and Density versus the Standard Normal Distribution

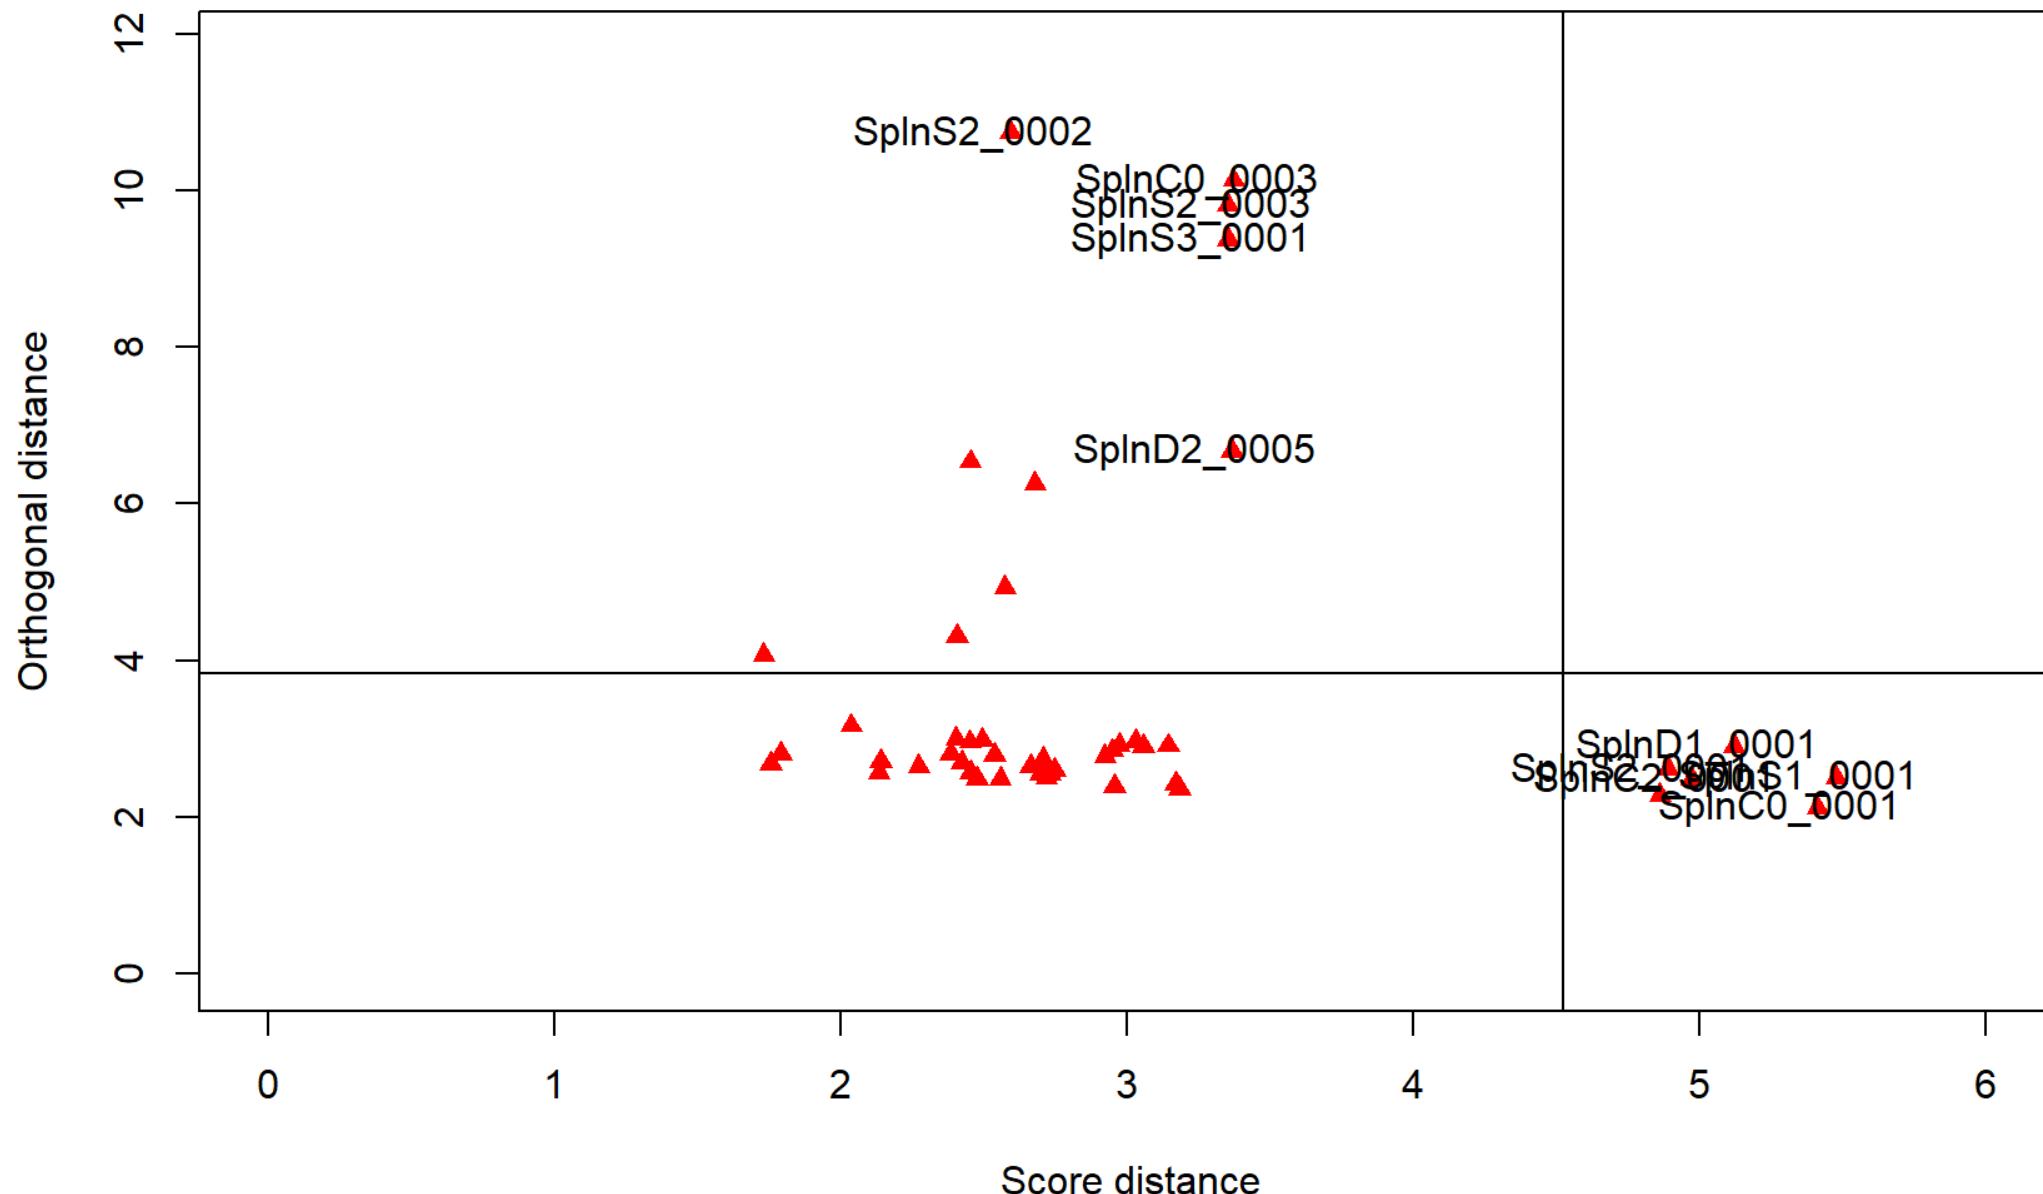

If CCC ≥ 0.8 (default parameter value), then outliers might be identifiable

If $SC < 0.25$ (default parameter value), then the sample might be an outlier

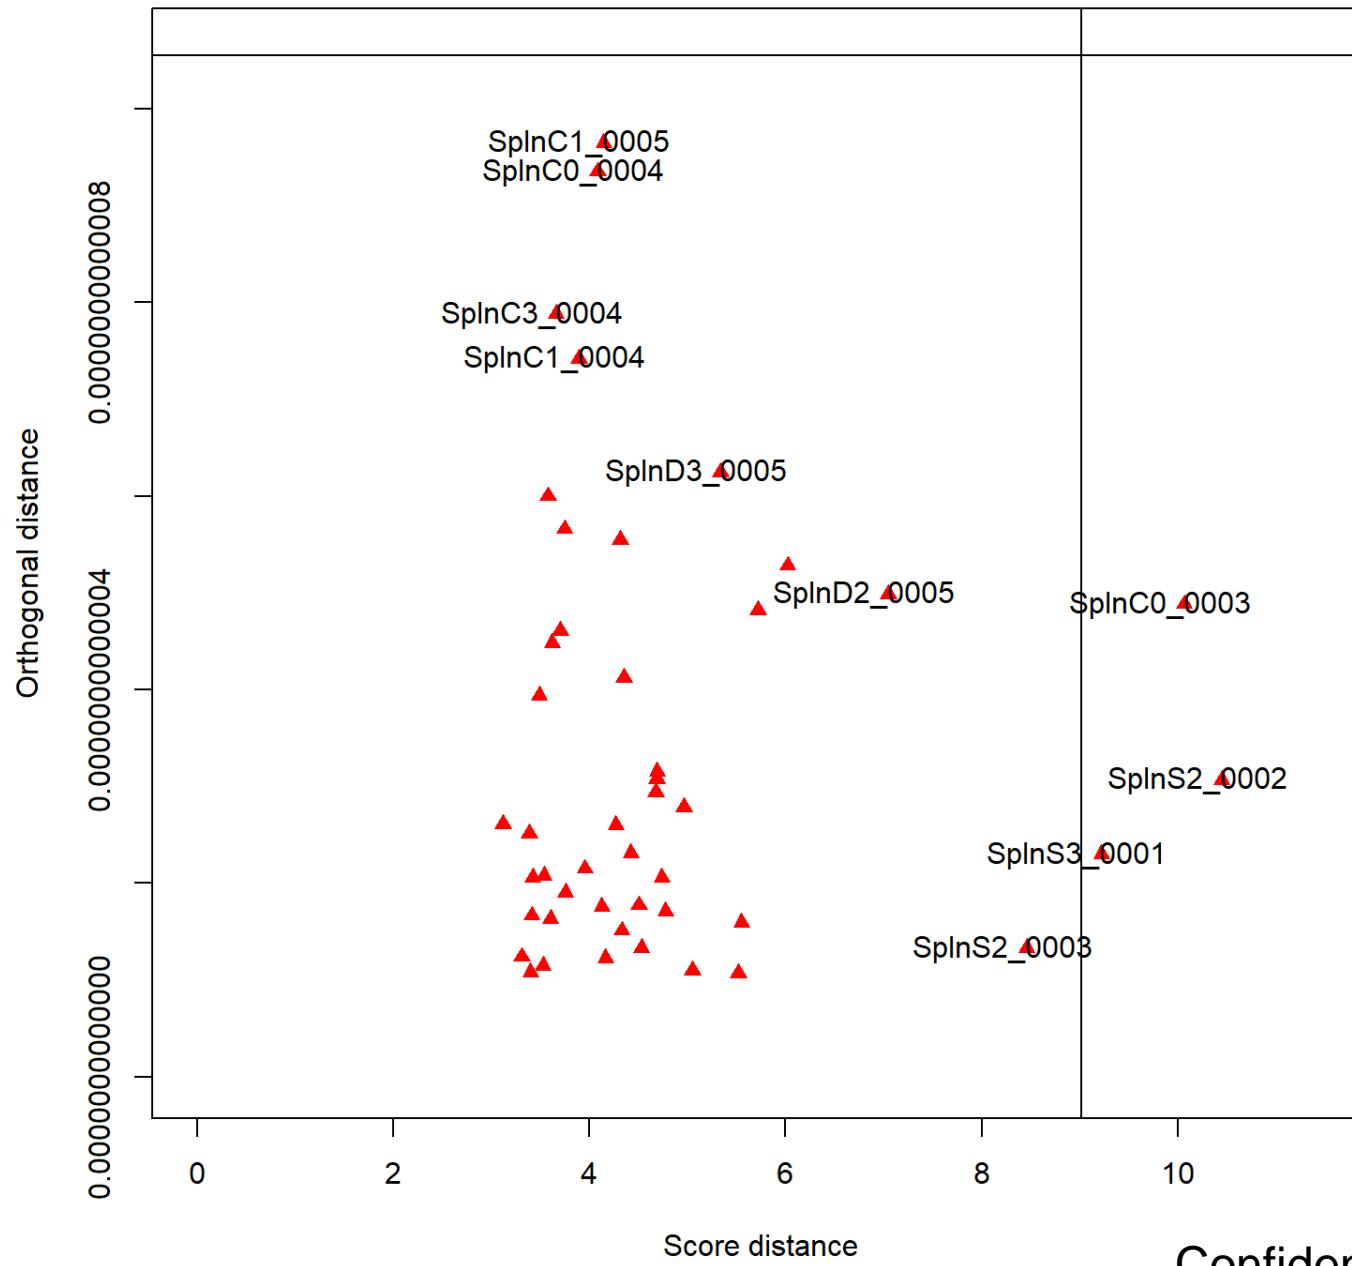

Robust PCA (robPCA)

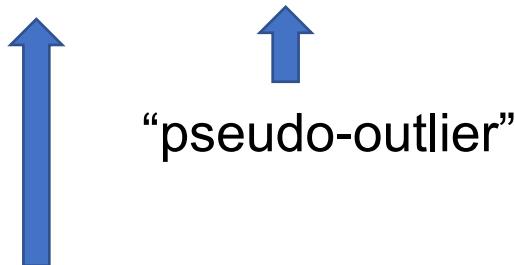

Confidence = 99.9% * 99.9% = 99.8%

Robust PCA (PcaGrid)

5.3 Outlier(s) Identified by Both HCA and Robust PCA

```
# The samples that satisfied all four criteria (CCC, SC, robpca, PcaGrid) for an outlier:  
if (CCC_df_ranked_top$CCC >= CCC_min) {  
  intersect(intersect(hcOutliers, rosOutliers), pcOutliers)  
}  
  
## [1] "SplnC0_0003" "SplnS3_0001"
```

One of the 20 uninfected samples

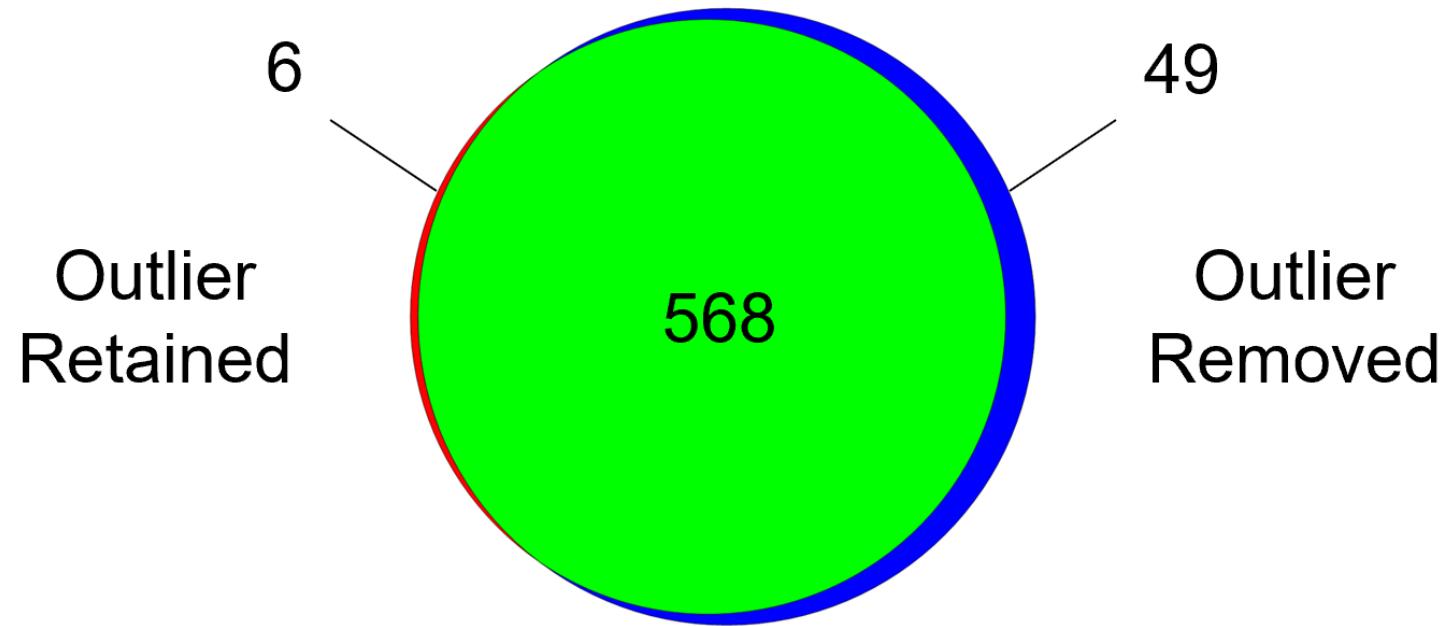

Could a single outlier among 20 negative control samples significantly impact downstream statistical analyses?

1-way ANOVAs were performed (q -value ≤ 0.05)

Both with and without including the true outlier SplnC0_0003

The pseudo-outlier SplnS3_0001 was not included in either set of ANOVA analyses

All of the uninfected mice were grouped into a single experimental condition

Detecting and removing the outlier apparently improved the accuracy of the results

Conclusions

- Outlier detection can help with:
 - Preventing erroneous biological conclusions
 - Improving experimental protocols
 - Discovering rare biological mechanisms
- EnsMOD incorporates two published algorithms for transcriptomics sample outlier detection
- EnsMOD can be used to analyze any omics dataset with ~normally distributed variance
- EnsMOD
 - Plots density curves
 - Measures data variance normality
 - Performs hierarchical cluster analyses
 - Performs robust principal component analyses
- EnsMOD successfully identified simulated outliers
- Phosphoproteomics sample outlier detection and removal resulted in additional ANOVA hits
- EnsMOD is free, open-source, easy to use, and published

Introduction to Principal Component Analysis (PCA)

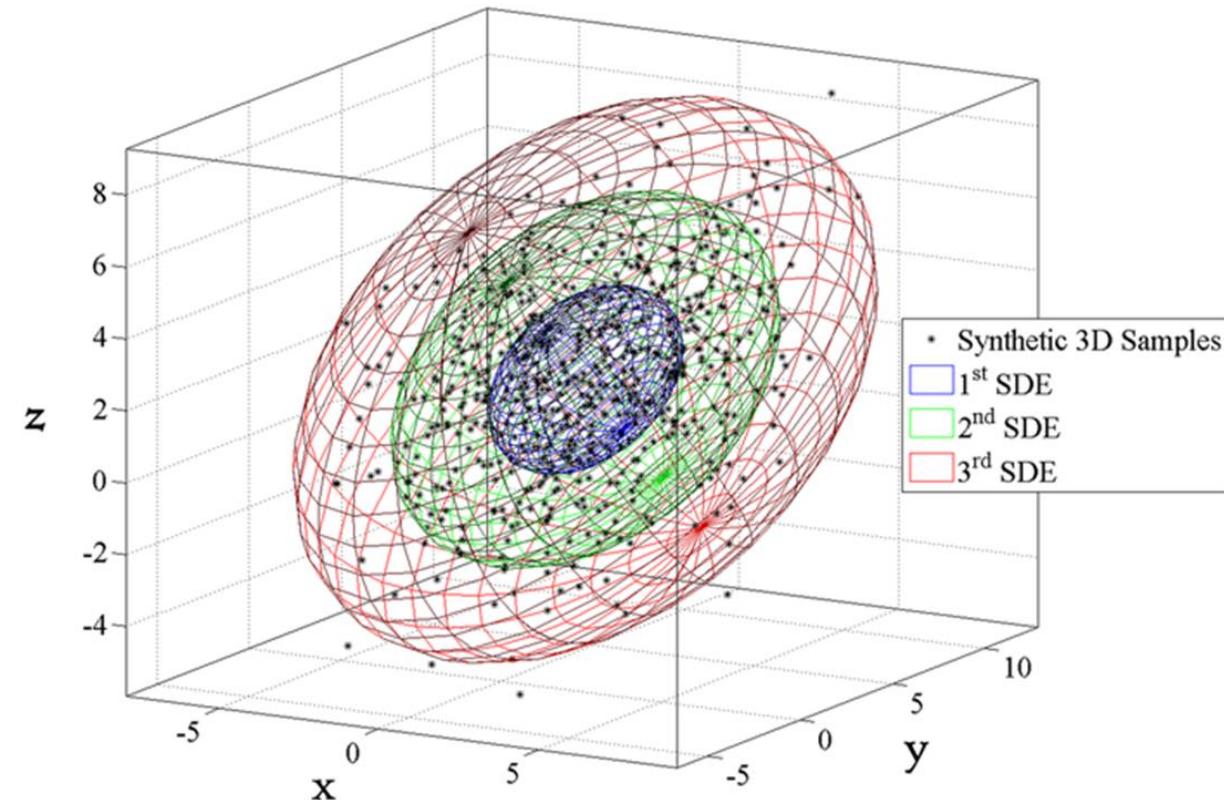

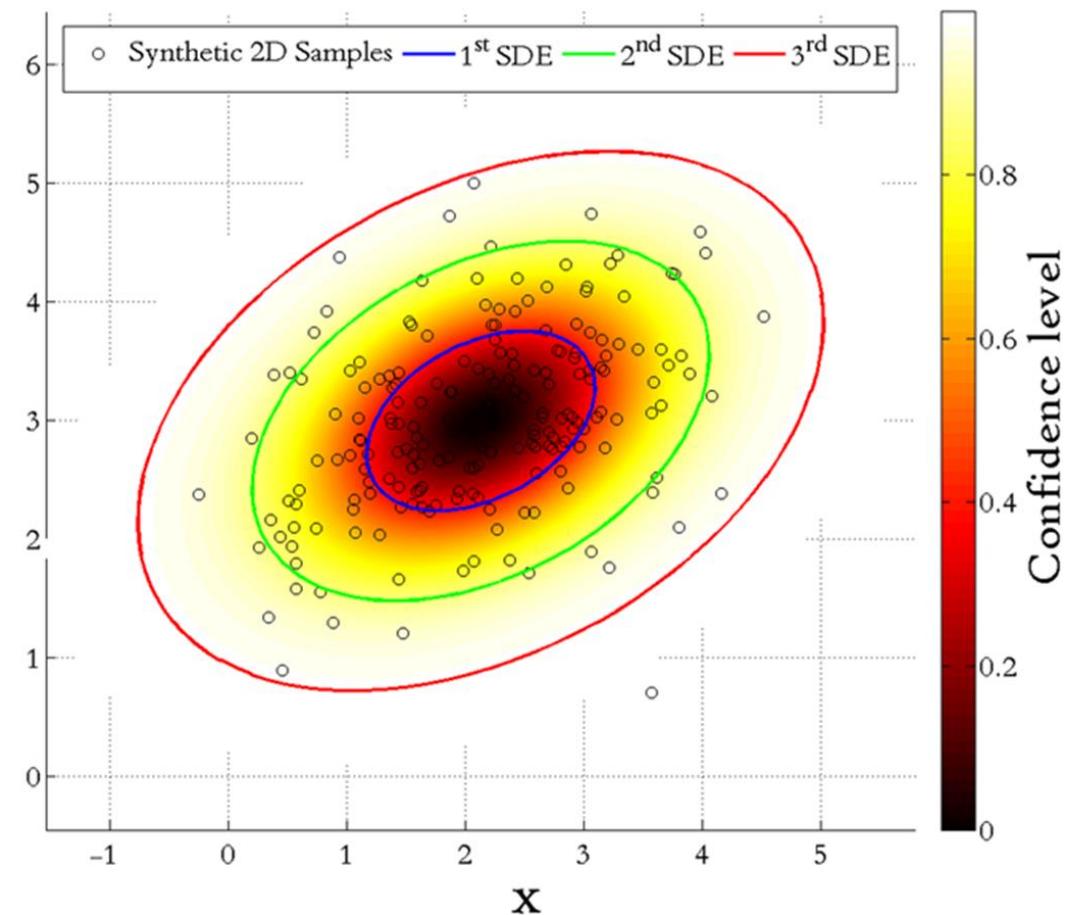

SD = standard deviation

PCA: mean center and rotate for maximum variance along PC1, then PC2, ..., then PCn

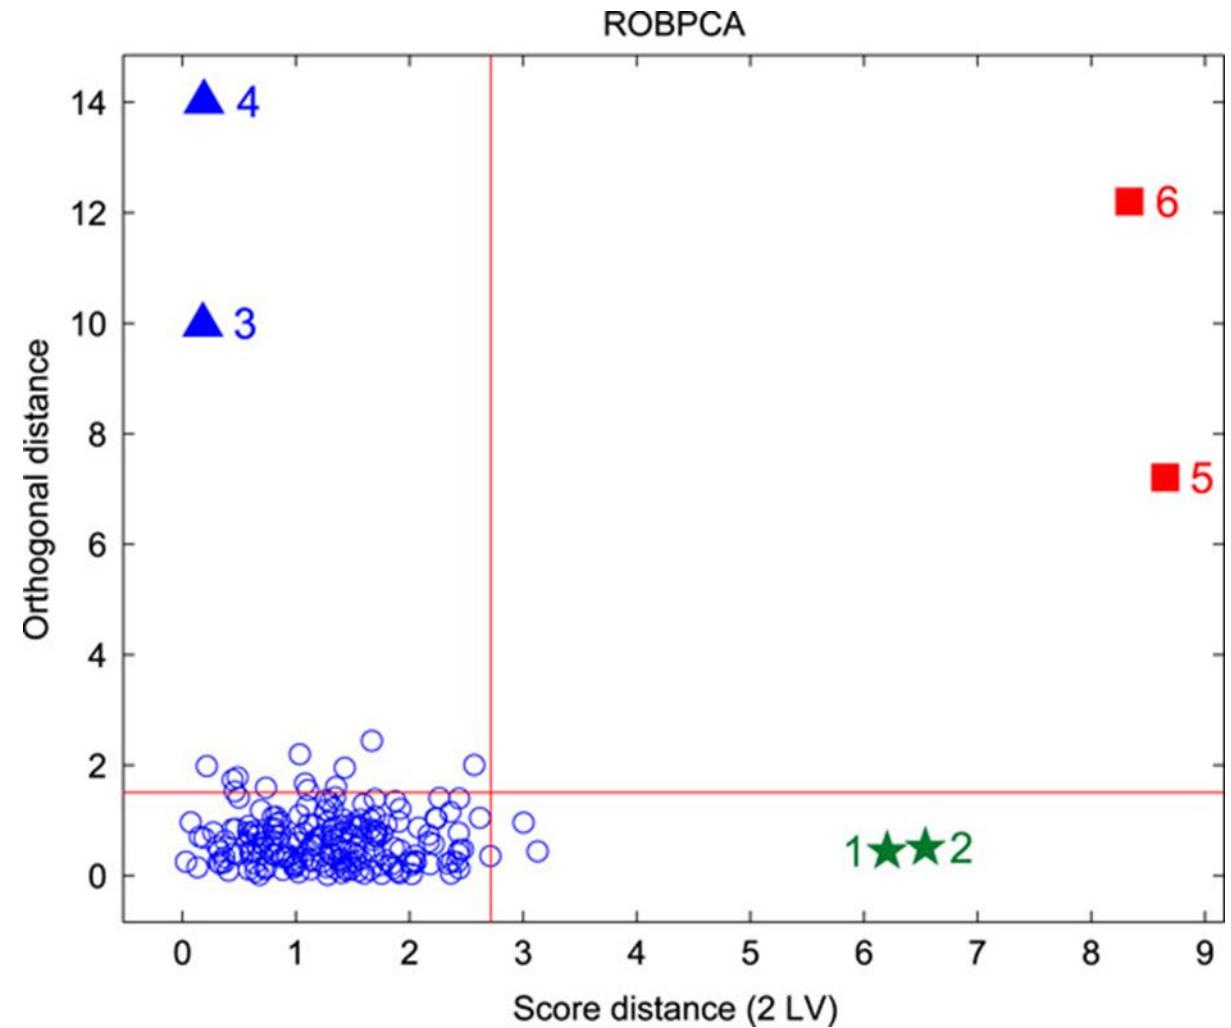

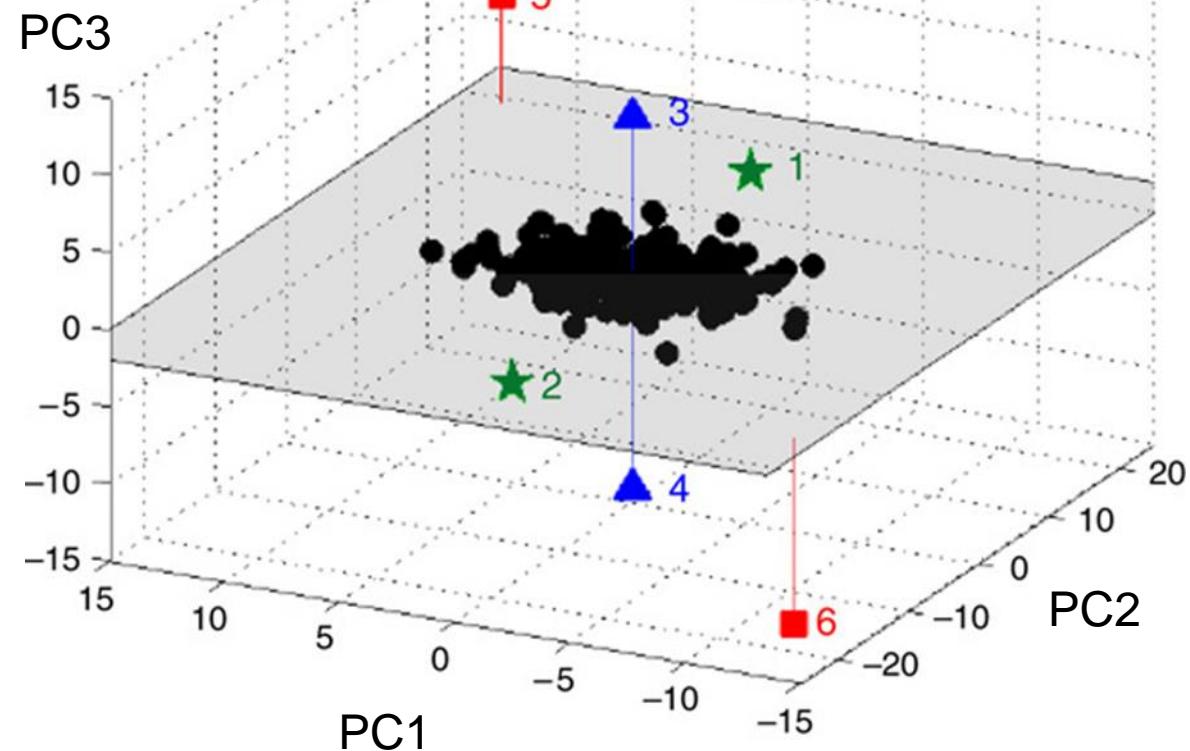

Robust PCA: a PCA algorithm that is insensitive to extreme points

Confidence Ellipse/Ellipsoid of a Multivariate Gaussian Distribution

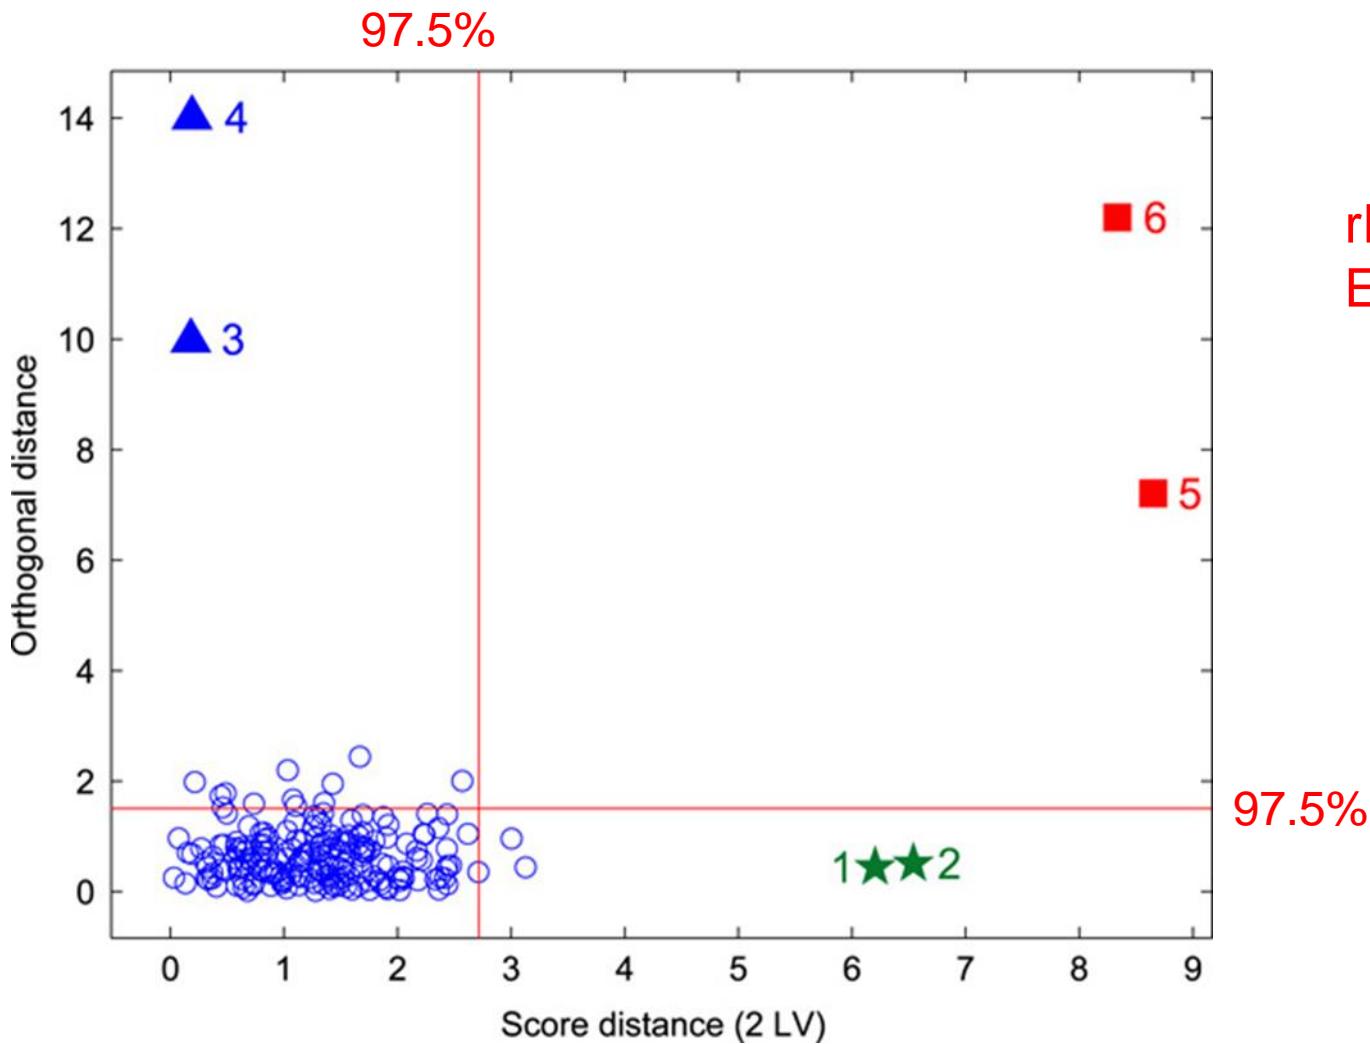

SDE = standard deviational ellipse

Example of an rPCA Distance-Distance Plot

rPCA parameter was set to 97.5%
Estimated Confidence = $(97.5\%)^2 = 95.1\%$

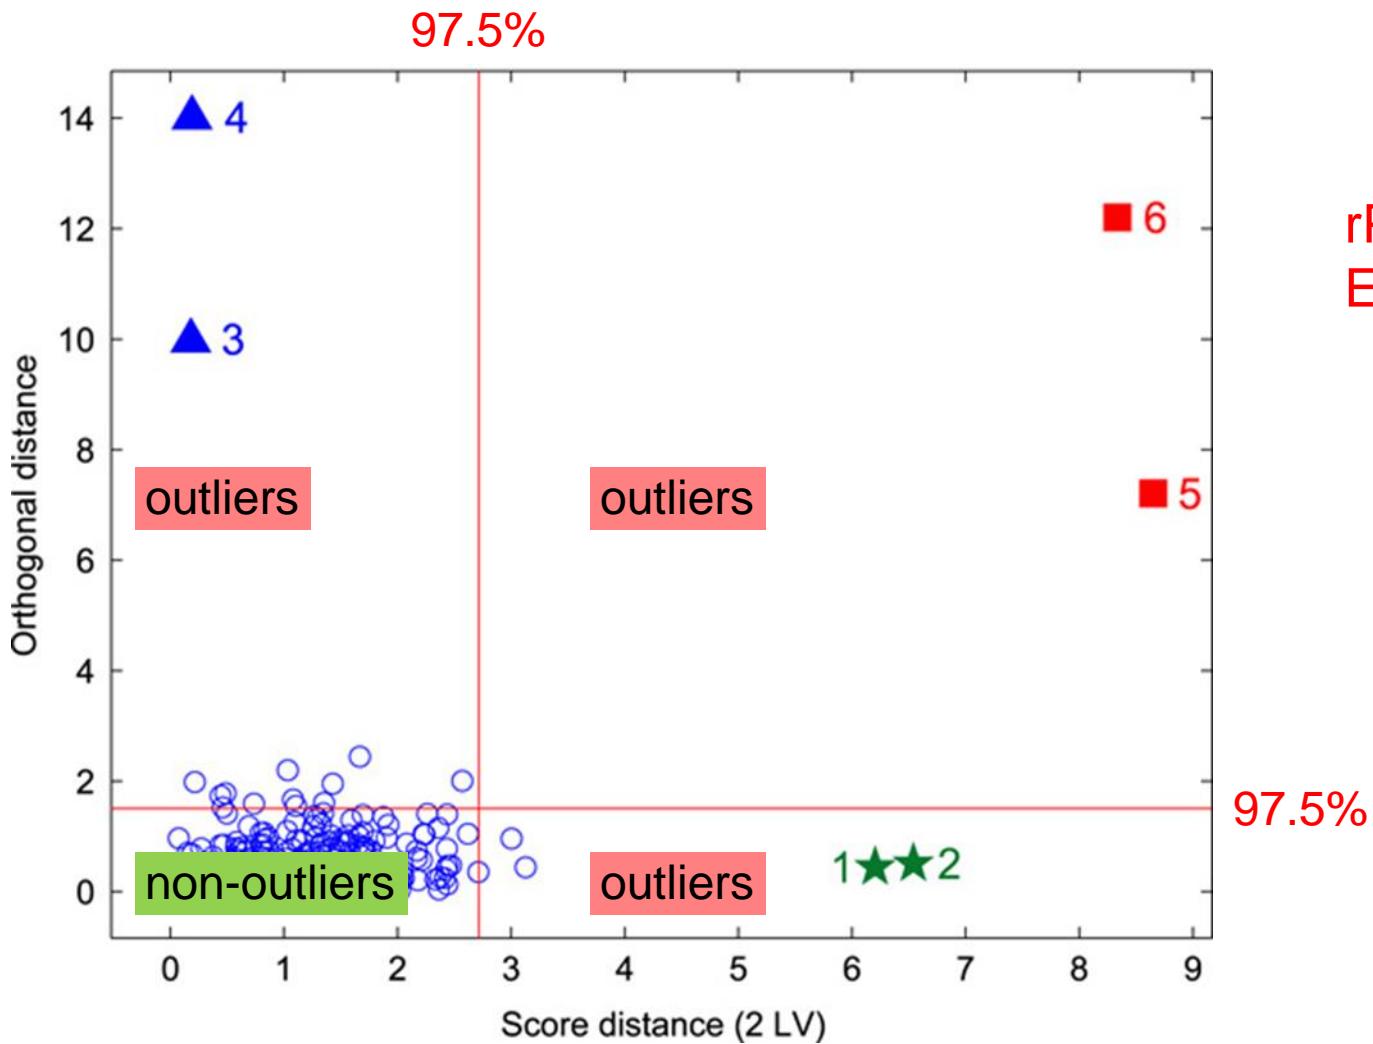

Example of an rPCA Distance-Distance Plot

97.5%

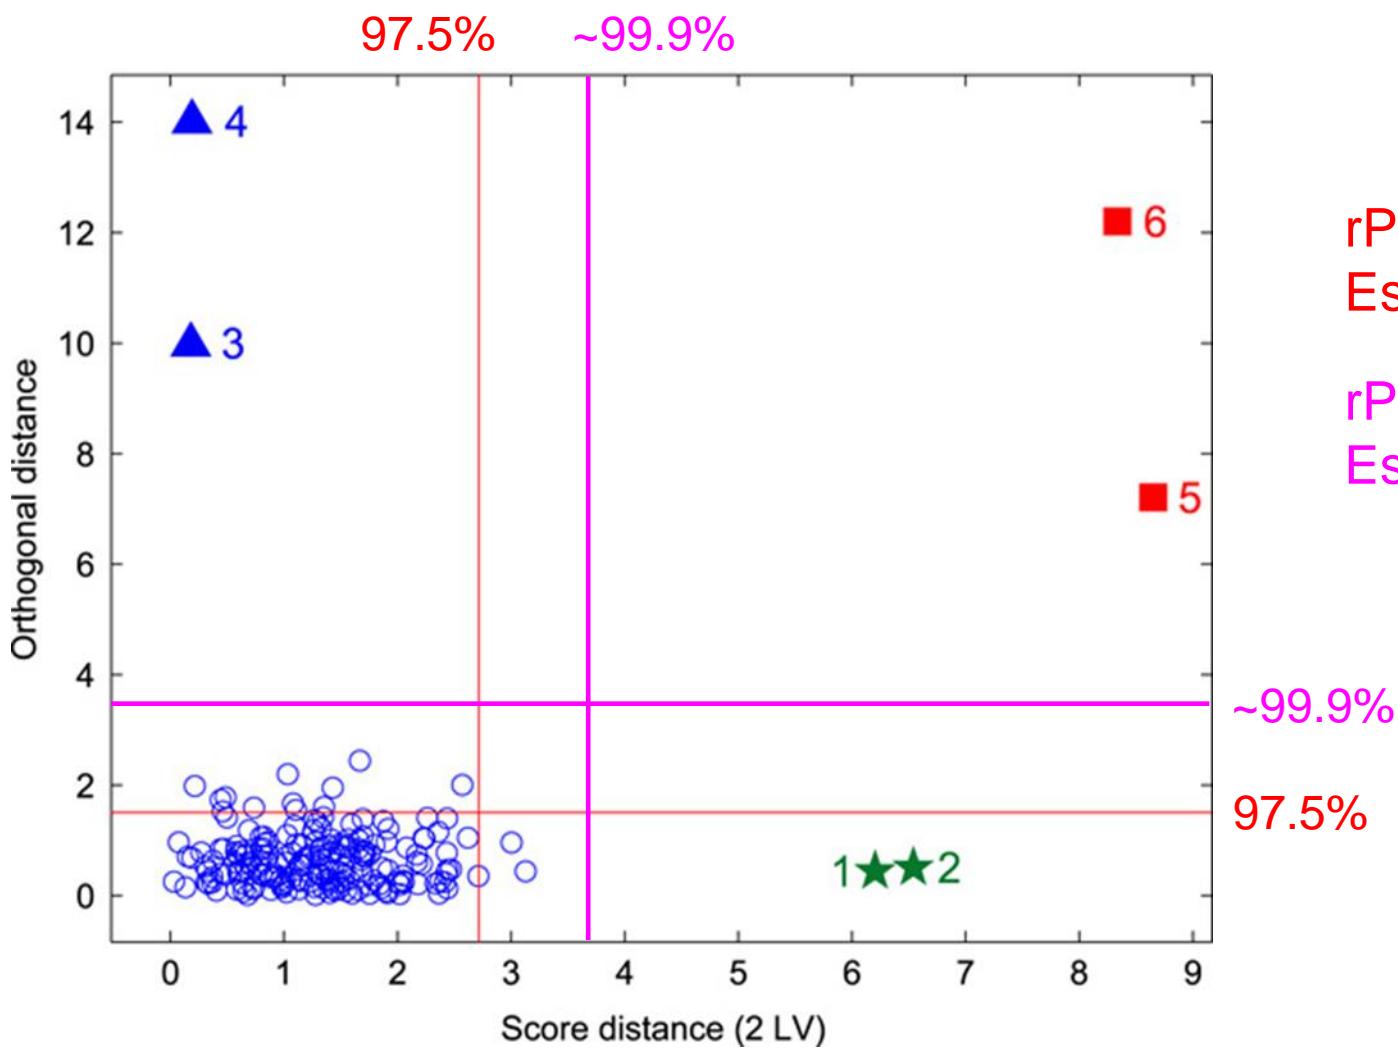

rPCA parameter was set to 97.5%
Estimated Confidence = $(97.5\%)^2 = 95.1\%$
